K. Okam del.

Gracilaria confervoides (L.) Grev. おごのり.

Gracilaria confervoides (L.) Grev.

Nom. Jap.: *Ogo-nori*.

PL. CLI.

Gracilaria confervoides (L.) Grev. *Alg. Brit. p.* 123; Harv. *Phyc. Brit.* t. 65; J. Ag. Sp. Alg. II, p. 587, *Epicr.* p. 413; Thur. et Born. *Etude Phyc.* t. 40; Hauck *Meeresalg.* p. 182, f. 77; De Toni *Syll. Alg.* IV., p. 431.—*Fucus confervoides* L. *Turn. Hist.* t. 84.—*Sphaerococcus confervoides* Ag. *Kuetz. Tab. Phyc.* XVIII., t. 72, and many other specis.—? *Syn. Gracilaria flexuosa* Holmes *New Mar. Alg. fr. Japan* (Linn. Soc. *Journ., Bot.* Vol. XXXI, 1895) p. 253.

Fronde numerous rising from a small callous disk, filiform, cylindrical, slightly flexuose, 5–20 cm. but sometimes extending to 60 cm. in length, usually less than 1 mm. in diameter or sometimes 1.5–2 mm., laterally branched, but very variable in length, thickness and somewhat in ramification. Branches mostly elongated, gradually tapering toward apex, beset with similarly shaped but shorter ones of the second order which are loaded with mostly simple, longer or shorter ramuli. Branches arise alternately on all sides with mostly patent or erect axils, sometimes quite naked and flagelliform or sometimes one-sidedly arising; in some here and there subdichotomous ramification is observed. Branches of every order taper toward apex and slightly constricted at their bases.—*Tetraspores* densely scattered over surface of frond. *Cystocarps* abundantly produced on all sides of branches, often aggregated, hemispherical; placenta elevated and not lobed. *Anthridial* holes are densely formed over surface of frond. *Frond* internally consists of larger, roundish, somewhat thick-walled cells. *Colour* purplish-brown, greenish or yellowish becoming blackish in drying. *Sub-*

stance cartilaginous and the plant often imperfectly adheres to paper in drying.

Hab.: On rocks, stones, shells, gravels, sticks etc.; those on the rocks of open shore are smaller in forms and those growing in brackish water in sheltered places are often very long. Widely distributed within the boundary of our country.

Gracilaria flexuosa Holm. is found to be nothing but the present species by my study on a specimen kept in the herbarium of Tokyo Imperial Museum at Uyeno. It is not clearly mentioned as the duplicate of the specimen sent to Mr. Holmes by Mr. Saida, but it bears the same number (no. 75) as that of the specimen sent to him. The specimen was so badly prepared as to have flexuose and alternate habit and from this Mr. Holmes seems to have been misled to rise it in a new species. I hope any one who has the convenience to study Holmes' specimen in question shall prove whether it is *Gracilaria confervoides* or not.

Gracilaria confervoides (L.) Grev.

お　ご　の　り

第 CLI 圖版

體ハ小サキ盤狀根ヨリ多數叢生シ、絲狀、圓柱狀、少シク雁木狀ニ屈曲シ、5-20 cm 長ク、時ニ 60 cm ニ起ユ、通常直徑 1 mm

ヨリ細ケレドモ時ニ1-2mmナルコトアリ、側面ヨリ分岐ス、然レドモ長サ、太サ甚シク異ナリ分岐法モ亦幾分異ナルコトアリ。枝ハ概テ長ク、漸次頂端ノ方ニ細ク、同様ノ形狀ナル短キ枝ヲ以テ圍マレ、其枝ハ更ニ概テ單狀ニシテ長キ又ハ短キ小枝ヲ存ス。枝ハ各方面ニ互生シ、腋概テ廣開シ又ハ狹シ、時トシテハ全ク小枝ナクシテ長ク鞭狀ヲナシ、時トシテハ一方ノ側ニ偏生ス、又或標本ニテハ其處此處稍又狀ニ分岐スル所アリ。各部位ノ枝ハ枝端細ク基部クビレタリ。—四分胞子ハ密ニ體ノ表面ニ散在ス。囊果ハ枝ノ周圍ニ多數ニ生ジ、往々集合シ、半球狀ナリ；胎座ハ球狀ニ隆起シ其表面ニ凹凸ナシ、雄性器ノ窠ハ密ニ體ノ表面ニ存ス。—體ノ内部ハ大ナル圓キ稍厚キ膜ノ細胞ヨリ成リ、厚キ皮層ヲ以テ蔽ハル；皮層ノ細胞ハ内方ヨリ漸次外方ニ小ナリ。色ハ褐紫色、帶綠又ハ帶黃色ニシテ乾燥スルトキハ暗紫色又ハ暗褐色トナル。質ハ軟骨質ニシテ、體ハ紙ニ附着スルコト往々不充分ナリ。

產地：岩石、礫、介殼、木杭等ノ上ニ在リテ高潮線ヨリ潮線間ニ在リ；外海ニ面シタル磯ニアルモノハ體形概テ小ナレドモ灣内ノ如キ靜ニシテ淡水ノ多キ所ニアルモノハ往々甚シク長シ。體質ハ產地ニヨリ硬軟一ナラズ。邦内占守迄殆ド隨所ニ之ヲ産ス。朝鮮。

用途：食用トシ、糊料トシ又凍瓊脂用トシテてんぐさニ混用ス。

分布：太西洋(スカンヂナビアヨリ Tinginニ至ル；西印度)；地中海；喜望峰；南洋諸島。

備考：Holmesガ伊豆下田ニテ齋田氏ノ採リタル *Gracilaria* ヲ *Gr. flexuosa* n. sp. トシテ發表シタルモノハ東京上野帝室博物館措葉室所藏標品ニ就テ予ノ調査スル所ヲ以テスレバ本種ニ外ナラズトス。該標品ニハHolmesニ送リタルモノナリトノ明

記ナケレドモ同氏ニ送リタルト同數ノ番號 (no. 75) ヲ附シアルヲ以テ多分同一品ノ副標品ナルベシト思惟ス。同標品ハ製作甚不良ニシテ恰モ互生スル如ク成レル爲メ Holmes ハ誤リテ新種ト認メタルモノニハ非ルカ尙ホ他日ノ研究ヲ俟ツ。

Spyridia elongata Okam. n. sp.

Nom. Jap.: *Naga-ubugé-gusa*.

PL. CLII, Fig. 4-13.

Diagn.: *Fronde* cæspitose, filiform, cylindrical, elongated, subtorulose at thicker parts, deliquescently dichotomo-alternate, fastigiato-flaccid, with lower branches more distantly set, and upper ones closer and beset with somewhat fusiform ramuli which are scattered or fasciculately arising. Branches almost destituted of ramelli except in apical portions, where a few of them are present; they are short and articulated, sparingly provided with genicular cells. Articulations of branches thoroughly corticated, and as long as or little shorter as broad. Fertile ramelli short and densely tufted. *Tetraspores* few, formed on the sides of ramellus. *Antheridia* formed all around ramellus. *Cystocarps* globular, shortly pedicelled.

Hab.: Washed ashore. Enoshima, Bōshyu, Kadzusa, Hitachi. Fruits:—March to May.

Many fronds rising from a broad circular disc., 20–45 cm.

Spirodia filamentosa (Wulf) Harv. うぶげぐき Fig. 1-3
Spirodia elongata Okam sp. n. ぶかうぶげぐき Fig. 4-13

high, about 1–1.5 mm. thick at the basal portion, gradually tapering above; branches not constricted at base, thickish, much wrinkled after drying. Plant when young abundantly provided with elongated and flaccid branches, but becoming barren, when old, dropping off most of them. Ramelli are sparingly present; a few of them arise on all sides on the apical portion of young ramuli. They taper toward both ends, short, 375–475 μ long, slightly incurved, round at apex, poorly provided with a single row of a few roundish genicular cellules which are mostly present at the external side of nodes, or often wanting. Their articulations are slightly constricted at nodes and subaequal to or little longer than broad. The cortical layer surrounding the central axis is thick, and it is internally composed of a few layers of larger oblong cells which become gradually smaller outward. Fertile ramelli bearing tetraspores and antheridia are densely tufted and antheridial ramelli form small cushion-like whitish flecks along the inner side of branches and mostly in axils. Colour dull pinkish or brickish red, becoming paler in drying. *Substance* thick and soft-cartilaginous. In drying, the thicker portion of frond becomes very much wrinkled; plant becomes brittle, and does not adhere to paper.

PL. CLII. Fig. 4–13. Fig. 4: old barren frond of *Spyridia elongata* n. sp. The end marked with \times is to be connected to the part with the same mark, $\frac{1}{1}$.—Fig. 5: portion of young frond; *a*, portion of branch bearing fusiform ramuli; $\frac{1}{1}$.—Fig. 6: ramellus, $\frac{22^0}{1}$.—Fig. 7: apex of a ramulus showing sterile ramelli, $\frac{3^4}{1}$.—Fig. 8: tetrasporic ramellus, $\frac{2^0}{1}$.—Fig. 9: antheridial fleck, $\frac{3^7}{1}$.—Fig. 10: cystocarp, almost sessile, $\frac{1^2}{1}$.—Fig. 11: pedicelled cystocarp, $\frac{2^2}{1}$.—Fig. 12: vertical section of cystocarp, $\frac{4^8}{1}$.—Fig. 13: 1–4, cells of the central axis; from the cells, 1–3, pericarpial cells are produced; from the cell marked, 4, spore filaments are developed, $\frac{22^0}{1}$.

By the way I have here to give the illustrations of fructified portions of *Spyridia filamentosa* Harv., which I have missed when I illustrated that species in Vol. III, no. 1, Pl. CII., fig. 5-14.

Tetraspores are formed from genicular cells surrounding the joints of ramelli and one or two spores are observed at the same joint. Antheridial cells are formed from genicular cells of ramelli and afterward a dense cluster is formed by their confluenting together over many articulations. *Cystocarps* globular attached to the side of branches or branchlets, with a short and very slender pedicel.

PL. CLII, fig. 1-3. Fig. 1: frond bearing cystocarps of *Spyridia filamentosa* (Wulf.) Harv. 1.—Fig. 2: tetrasporic ramellus, $\frac{145}{1}$.—Fig. 3: antheridial fleck (from an American specimen), magd.

*Spyridia*¹⁾ *elongata* Okam. 新種

ながうぶげぐさ 岡村稱

第 CLII 圖版, 4-13 圖.

性質: 體ハ叢生シ, 絲狀, 圓柱狀, 長ク, 太キ部分ハ稍念珠狀ニクビレ, 叉狀トモ互生トモナク漸次分岐シ, 枝ハ幾分直立スル如クニテ柔ク, 下部ノ枝ハ互ニ距リ上部ノ枝ハ密ニシテ兩端ニ稍細クナレル小枝ヲ存ス; 小枝ハ散在シ又ハ集リテ出ヅ. 枝ハ殆ド毛狀小枝(即チ短條小枝)ナク, 唯少シク頂端ニ之ヲ存ス; 毛狀小枝ハ短クシテ, 關節シ, 其節部ニハ僅ニ横ニ小細胞ヲ存ス. 枝ノ關節ハ全部皮層細胞ヲ以テ蔽ハレ, 太サト關節細胞ノ長サト殆ド相同ジク, 或ハ少シク短シ. 實ヲ有スル毛狀小枝ハ短クシテ密集ス. 四分胞子ハ僅ニ生ジ, 毛狀小枝

1) うぶげぐさ屬, *Spyridia* Harv., ノ性質ハ第三卷9頁ニ在リ.

ノ側面ニ着ク。雄性細胞ハ毛狀小枝ノ全周ニ生ズ。囊果ハ球狀ニシテ短柄ヲ有ス。

產地：海濱ニ打揚ゲラル(多分低潮線以下ニ産スルナルベシ)。相州江ノ島，房州，上總，常陸。果實：三月—五月。

體ハ多數廣キ圓盤狀根ヲ以テ立チ，20-45 cm 高ク，下部約1-1.5 mm 太ク，漸次上方ニ細ク，枝ハ基部クビレズ，稍太ク，乾燥スルトキハ縦ニ皺ヲ生ズ。體ハ幼キ時ハ澤山ニ柔カキ長キ枝ヲ有スレドモ，老成スルトキハ枝ノ脱落スル爲メ裸トナル。毛狀小枝ハ僅ニ存シ，幼キ小枝ノ頂部ノ周圍ニ少シク之ヲ見ルベシ。毛狀小枝ハ兩端ニ細ク，短ク，長サ375-475 μ アリ，少シク内方ニ屈曲シ，頂端圓ク，節部ノ小細胞ハ僅ニ之ヲ存ス；其小細胞ハ概テ節部ノ外側ニ生ジ或ハ往々之ヲ欠ク。毛狀小枝ノ關節ハ節部ニ於テ少シククビレ，太サト同ジ位若クハ少シク長シ。中軸ノ周圍ニ在ル皮層ハ厚クシテ其内層ハ大ナル長楕圓狀ノ細胞二三層ヨリ成リ外方ニ漸次小ナリ。—四分胞子及雄性細胞ヲ熟シタル毛狀小枝ハ密集シ，雄性細胞ヲ着ケタルモノハ小サキ低キ白色ノ隆マリヲ作リテ枝ノ内側ニ存シ概テ腋ノ所ニ多シ。色ハ淡赭色又ハ赤煉瓦色ニシテ乾燥スルトキハ幾分白色トナル。質ハ多肉ニシテ軟骨質ナレドモ軟弱ナリ。乾燥スルトキハ太キ部分ハ甚シク皺ヲナシ，體ハ脆クナリ，紙ニ附着セズ。

第 C.II 圖版，4-13 圖。4：ながうぶげぐさ，*Spyridia elongata*，新種，ノ老成モノ枝少ナキ體；×印ノ部分ハ接續スベキ印ナリ， $\frac{1}{1}$ -5：幼キ體ノ一部；a，兩端細クナリタル小枝ヲ示ス， $\frac{1}{1}$ -6：毛狀小枝， $\frac{2}{1}$ -7：小枝ノ頂端ニ毛狀小枝ヲ生ズル狀， $\frac{2}{1}$ -8：四分胞子ヲ有スル毛狀小枝， $\frac{2}{1}$ -9：雄性器理， $\frac{2}{1}$ -10：殆ド無柄ナル囊果， $\frac{2}{1}$ -11：短柄アル囊果， $\frac{2}{1}$ -12：囊果ノ縱斷面， $\frac{2}{1}$ -13：1-4，中軸細胞；1-3ノ細胞ヨリハ果皮ヲ形成スル細胞ヲ生ジ；4ノ細胞ヨリハ胞子ヲ形成スル胞子絲ヲ生ズ， $\frac{2}{1}$ -10。

序ヲ以テ茲ニ *Spyridia filamentosa* (Wulf.) Harv., うぶげぐ

Homoeostroma latifolium (Born.) J. Ag.

Nom. Jap.: *Haba-modoki*.

PL. CLIII.

Homoeostroma latifolium (Born.) J. Ag. Anal. Alg. Cont. III., p. 11;
Saunders Phycol. Mem. p. 159, Pl. XXX.—*Punctaria latifolia* Bornet Etud.
p. 13, Pl. V.—*P. latifolia* Grev. Hauck Meeresalg. p. 371, f. 158.

Fronde caespitose, thin (172 μ thick) and leaf-like, 10–16 cm.
long, 3–7 cm. broad, simple, narrow or broadly lanceolate, some-
times tapering toward apex, mostly blunt, much undulated, some-
times undulato-lobed, cuneate, ovate or cordate at base with very
short stipe, densely scattered over surfaces with minute dark
brownish dots. Frond is constructed of one sort of cells, rectan-
gular in shape, that is the outer and inner cells are of equal size
and shape and they are superposed one upon another mostly in 4,
sometimes 5–6 layers. The lower portion of frond is thickened
(360 μ thick) and consists of many more layers of cells. In
fructified portion I have seen cortical and infracortical cells original-

ly corresponding to the one of the inner layer to be divided into two or more. For example, fig. 10 shows such a section which has the sterile portion consisting of 2-3 layers of cells of equal size. *Zoosporangia* are spherical and isolated. *Gametangia* globular or slightly prominent. *Colour* light yellowish-olive. Plant pretty well adheres to paper in drying, but older ones not.

Hab.: Hirado (near Nagasaki); Provs. Ise, Mikawa, Noto, Sado; Goi (Prov. Kadzusa).

In fig. 2 I have illustrated small lanceolate fronds from material collected at Goi, in Tokyo Bay, among which there were many larger and broader and round-headed fronds.

PL. CLIII. Fig. 1: fronds of *Homœostroma latifolium* (Born.) J. Ag. (from Prov. Mikawa), $\frac{1}{1}$.—Fig. 2: fully grown smaller fronds in Tokyo bay (Goi, Prov. Kadzusa), $\frac{1}{1}$.—Fig. 3: cross-section of the lower thickened portion (same as fig. 1), $\frac{34}{1}$.—Fig. 4: middle portion of fig. 3 (360 μ thick), $\frac{80}{1}$.—Fig. 5-6: different parts of the same cross-section of a frond, showing hairs in one of them, $\frac{353}{1}$.—Fig. 7: surface view of the sori o-gametangia, $\frac{48}{1}$.—Fig. 8: sorus of gametangia, magd., $\frac{220}{1}$.—Fig. 9: cross section of frond bearing gametangial sori, $\frac{353}{1}$. (Fig. 5-9, from Goi in Tokyo Bay, March, 3, 1915).—Fig. 10: cross-section of frond bearing zoosporangia, (172 μ thick, from Prov. Mikawa). (Fig. 1, 3-4, and 10, from Prov. Mikawa).

Caulerpa Okamurai Weber-van Bosse.

Nom. Jap.: *Fusa-ikwadzuta*.

PL. CLIV, Fig. 1-8.

Caulerpa Okamurai Weber-v. Bos. in Okam. Alg. fr. Ogasawara-jima
 (Bot. Mag. Tokyo, Vol. XI, No. 119), p. 5, Pl. I, f. 13-14; Weber-v. Bos.
 Monogr. Caul. p. 385, Pl. XXXIV, fig. 9; Okam. Alg. Jap. Exsic. Fasc.
 I, no. 48.

“*Fronds* arise from surculus, often two near together, and are cylindrical, being simple, or branching irregularly once or twice. They attain a height of 4-17 cm., being as thick as the surculus and are clothed throughout their whole length with more or less densely imbricated ramenta. Ramenta are apparently imbricated in densely clothed fronds, while in loosely inserted ones they appear as if distichous and opposite. The latter disposition of ramenta is more generally the case in those standing near the base of frond, where ramenta are as a rule loosely inserted; they are gradually imbricated and become closer as they proceed upward. Rachis is slightly constricted at the insertion of ramenta and somewhat bulges out laterally beneath the constriction, giving rise to a short pedicel on which a ramentum is situated. The junction of a ramentum and a pedicel is more distinctly constricted

than the constriction of the rachis. The form of ramenta varies in several fronds. Basal ones are generally shorter than the upper and they are obovate, while the upper ones are oblong or subclavato-cylindrical, their apical portion being a little thicker than their basal portion. They attain a length of 2–5 mm. being ca. 1.5 mm. thick, that is subequal to diameter of the rachis. *Color* of plant is grass-green, which is well preserved in drying, or in older fronds it fades to a dull straw color. *Substance* is soft and the plant imperfectly adheres to paper in drying.”—Okam. *l. c.*

f. **oligophylla** Okam. n. f. Pl. CLIV., Eig. 7.

Syn.? *Caulerpa tateyamensis* Yendo Three New Mar. Alg. fr. Japan. (Bot. Mag. Tokyo, Vol. XVII, p. 99, Pl. III, f. 1–3).

Fronds much elongated, often 15 cm. long or more, irregularly branched; ramenta almost none or very few present, sometimes here and there a little imbricated which are pedicelled as the type species or sessile.

The present plant is evidently an aberrant form of *C. Okamurai*, as is shown by the nature of ramenta. It is abundantly obtained by trawling in the water 2–3 fathoms deep at Bay of Tateyama, Prov. Bōshyu, where the type-form is also observed. Mr. Yendo described a *Caulerpa* from the same locality as a new sp., *C. Tateyamensis*, which is probably same as the form here mentioned, though I am not able to see his specimen.

Caulerpa fastigiata Mont.

Nom. Jap.: *Ki-iwadzuta*.

PL. CLIV, Fig. 9-13.

C. fastigiata Mont. *Flora Cuba* Pl. 2, fig. 3; J. Ag. Till Alg. Syst. p. 5; Weber-v. Bos. Monogr. Caul. p. 262, Pl. XX., f. 1-2; Vickers Phyc. Barbadiensis tab. 36; Börges. Some Chlorophyc. from the Dan. W. Ind. (Bot. Tidsskr. 31 Bd., p. 127; Reinke Ueb. Caul. p. 6, f. 1-2; De Toni Syll. 1., p. 442.—*Herpochaeta fastigiata* Mont. Ann. d. Sc. Nat. 2me. Ser. Vol. 20, p. 305; Kuetz. Tab. Phyc. VI, t. 1.

Fronds with naked and slender surculus sending root-fibres below and aerial shoots upwards. Aerial shoots simple, subdichotomous or alternately branched, fastigiate, ca. 3 cm. high, loaded with sometimes many and closely set, sometimes few and scattered ramuli which are opposite, alternate or subverticillate standing in different directions; they are longer or shorter, usually cylindrical or slightly swollen toward the obtuse apex. All the parts are slender and there is no difference in thickness between surculus and erect branches.

Hab.: Ishigaki-jima (Ryukyu; leg. M. Tago).

In our plant the upper half of aërial shoots is more intensely colored as Mr. Börgesen and Mme. Weber van Bosse already stated.

PL. CLV, Fig. 1-3.

C. cupressoides Ag. var. *lycopodium* f. *amicorum* Weber-van Bosse Monogr. *Caulerpa* p. 337, Pl. XXVII, fig. 12, Pl. XXVIII, f. 10-12.—*C. amicum* Harv. Proc. Amer. Acad. Vol. IV, 1869.

Plant large and robust with thick and glabrous surculus (ca. 2-3 mm. in diameter). Aerial shoot erect, 10-15 cm. high, naked and cylindrical below for longer or shorter distance appearing like stipe, loosely branched in alternate or sometimes subfasciculate manner, standing on narrow or patent axils, densely covered with subulate, incurved patent and subcylindrical rammenta arranged in 2-4-5 rows generally 2-2.5 times as long as the diameter of rachis, while those at the base of shoot shorter and conical. Plant becomes stiff in drying and does not adhere to paper.

f. *disticha* Weber-van Bosse.

PL. CLV, Fig. 5-8.

C. Webbiana Mont. f. *disticha* Web.-v. Bos. Monogr. Caul. p. 270, Pl.

XXI, f. 1; Børgesen An Ecol. and System. acc. of the Danish W. Ind. (Mem. Aad. Roy. d. Sc. etc.) 1907, p. 357, f. 4.

Fronde small with erect shoots bearing distichous rows of opposite ramenta, 5-10-13 mm. long. Our specimens being dried and pressed the compressed habit of frond is not clear; but ramenta are compressed with the flat surface on the same plane with that of shoot. Ramenta are wedge-shaped with the broadest end turned outward, and several times dichotomously divided ending in a small spine, very widely parted; the broadest distance between the extremities of ramenta on both sides is 1-1.8 mm. The erect shoots show a very distinctly rhythmical growth of ramenta, as Børgesen states; thus every set of 3 or 4, sometimes 5 or 6 continuous pairs of ramenta gradually decrease in lengths from below upward, alternating in a regular sequence.

Helminthocladia australis Harv.

Nom. Jap.: *Beni-modzuku*.

PL. CLVI—CLVII, Fig. 7-21.

Helminthocladia australis Harv. Phyc. Austr. V, tab. 272; J. Ag. Epicr. p. 506; Id. Till Alg. Syst. XI, p. 39; De Toni Phyc. Jap. Nov. p. 20; Id. Syll. Alg. IV, p. 83.

Root a small fleshy disc. *Fronde*s caespitose, cylindrical, sometimes compressed or irregularly rugulose longitudinally in very robust frond, with main stem attaining a breadth of 10-15 mm in broader compressed portion, 15-45 cm long, tapering at base for a short distance like stem, soon thickening into a diameter of 2-4 mm in the middle portion and thence upward gradually attenuating. Main stem mostly simple or once or twice forked or parted, closely set through its whole length with widely patent branches, half as thick as main stem, with longer or shorter ones mixed. Branches worm-like, usually not attenuated at base, tapering to a slender apex, either quite simple or once or twice irregularly branched, and furnished with lateral simple or forked branchlets. Branchlets are sometimes very short, much slender and densely arising, often curled as shown in the lower portion of PL. CLVI.

Plant is dioecious. Antheridia are produced from the terminal cells of the peripheral moniliform filaments. *Procaryps* consisting of 3-5 cells are formed as a lateral branch of peripheral filaments near their bases. *Cystocaryps* situated among the peripheral filaments consisting of a globular mass of spores. Tetraspores unknown. *Color* vinoso-red or purple, soon fading to brick-red in freshwater. *Substance* gelatinoso-cartilaginous, tough and elastic, very soft and

lubricous. In drying the plant closely adheres to paper.

Hab.: On rocks or stones between tide marks extending to low tide. (4–11 fath.) Pacific coast from Kagoshima to Matsu-shima (Prov. Rikuzen), and Prov. Idzumo, Tango and Noto. Chip-pen (Chosen). Fruits: Spring—early summer.

Harvey in *l. c.* remarks under *Helminthocladia australis* "My only doubt respecting it is, lest it should not be sufficiently distinct specifically from *H. purpurea* itself, which is a very variable plant, and to some of whose varieties our plant bears considerable resemblance. In general, there is more difference in diameter between the main stem and its branches in the European [*H. purpurea*] than in the Australian plant [*H. australis*]." According to his opinion I refer the present plant to *H. australis*. It would be proved, however, in other days, to be natural to unite the two related plants in one and the same species. A form having much slender branchlets, as shown in the lower portion of PL. CLVI, I think to be a form stunted from the cause of its localities where terminal flow of cold current visits.

PL. CLVI. Fully grown frond of *Helminthocladia australis* Harv.; below with a portion of frond having much shorter and slender ramuli, I/I.

Odonthalia semicostata (Mert.) J. Ag.

PL. CLVII, Fig. 1-6.

Od. semicostata (Mert.) J. Ag. Sp. Alg. II, p. 898; De Toni Syll. Alg. IV, p. 1141.

Fronde flat rising from scutate disc, broadly linear, 10-15 cm high, 3-5 mm broad in branches, much broader in the main portion, often attaining 5-8 mm or more, decompound pinnate, alternately dentate along both margins, traversed by more or less flexuose faint midrib which evanescently disappears upward (in Fig. 1, the midrib is represented too distinctly) and thickens below for a short distance like stem. *Lacineae* are dentate or deltoideo subulate, erect or parted in lower part, but subfalcate near apices of branches. Veins running from the midrib to marginal *lacineae* alternate faintly, but stand opposite here and there where branches and *lacineae* oppose to each other. *Ramuli* arise in the axils of *lacineae*, three or more in one row above an axil, often densely aggregated, and some of them grow up into branches. *Fruits* unknown. *Color* brick-red with purplish tint in dried state and somewhat dusky. *Substance* membranaceous and the plant rather closely adheres to paper in drying.

Hab.: floating 10 miles off the mouth of the *Riv. Osernaya*

in the western coast of Kamchatka, some 35 miles north of C. Lopatka.

The present plant has a strong resemblance with *Odonthalia semicostata* illustrated in Setchell and Gardner's *Algae of North-western America* p. 336, pl. 26,27, in having closely arranged alternate dentiform to subulate lacineae along margins of branches; but the mode of ramification and presence of axillary branches differ from it. The authors illustrate regularly alternate branches which have no pinnule standing in axils and the substance is said as thick. J. Agardh (*l.c.*) describes *Oa. semicostata* Mert. from Kamchatka as having thin membranaceous frond bearing minute pinnulae in axils. Collins (*The Mar. Alg. of Vancouver Island*, 1913, p. 122) considers Setch. and Gardn.'s plant as a species different from that of J. Agardh, probably on account of thicker substance, alternate ramification and absence of axillary pinnulae. Taking into consideration the locality of Mertens' plant is same as that of ours which has much resemblance with J. Agardh's descriptions, I refer our plant to the present species, though I have not seen any reliable specimen or illustration of the species.

PL. CLVII, fig. 1-6. Fig. 1: sterile frond of *Odonthalia semicostata* (Mert.) J. Ag. on the frond of *Ptilota asplenioides*, $\frac{1}{1}$.—Fig. 2: holdfast embracing the frond of *Pt. asplenioides*, a ; $\frac{12}{1}$.—Fig. 3: growing apex of frond; a , apical cell; b, b' , lacineae; $\frac{353}{1}$.—Fig. 4: cross-section of frond; c , central axis; c' , vein; $\frac{48}{1}$.—Fig. 5: costal portion of fig. 4. magd.; c , central axis; $\frac{220}{1}$.—Fig. 6: longitudinal section of frond, $\frac{48}{1}$.

Nemalion vermiculare Sur.

Nom. Jap.: *Umi-zomen*.

PL. CLVIII, Fig. 1-16.

Nemalion vermiculare Sur. Illustr. Alg. du Japon I, p. 91, tab. XXXIV; Hariot Alg. de Yokoska, p. 218, n. 24; De Toni Syll. Alg. IV, p. 78; Id. Phyc. Jap. Nov. p. 19.

*Fronde*s simple or sparingly branched or splitted, vermicular, very soft and slippery, 10-20 cm. long, 1.5-2 mm. thick, deep vinoso-red fading to yellowish in age. Central strand mostly slender and as thick as $\frac{1}{2}$ - $\frac{1}{3}$ of the length of peripheral filaments whose upper articulations are less moniliform and a little elongated or almost cylindrical. Dioecious. *Substance* gelatinoso-cartilaginous and the plant closely adheres to paper in drying.

Hab.: On rocks between tide marks near high tide; Pacific coast from Kyushyu to Prov. Mutsu; Otaru, Teshiwo; between Prov. Idzumo and Prov. Yechigo; Sado Isl. Sekito (Chosen). Fruits: early summer.

In external appearance the plant is difficult to distinguish from *N. lubricum*, but as Suringar stated, the thickness of central strand of the former is much more slender than that of the latter; moreover the upper articulations of peripheral filaments are less moniliform

and much elongated than those of *N. lubricum*. After the establisher's opinion I put the plant under the present species. However, I can not help to doubt whether the plant should not be a local form of *N. lubricum*.

Callophyllis crispata Okam.

Nom. Jap.: *Hiroha-no-tosakamodoki*.

PL. CLIX, Fig. 1-5.

Callophyllis crispata Okam. Contr. Knowl. Mar. Alg. Jap. II. (Bot. Mag. Tokyo, Vol X, 1896), p. 21, pl. III, 1, 2.

“Plants rising from a callous disc, solitary or few tufted shortly stipitate, 10-20 cm high or more. Stipe compressed or almost cylindrical, afterward either simple or divided, giving rise to many main divisions and soon expanding into narrower or broader cuneate base of frond. Frond divided in di-polytomous often palmato-flabellate manner, and again decomposed in a

similar way; so that the outline of frond, when placed in expansion, forms a large segment of a circle. Segments broadly linear cuneate, more or less expanding beneath forks, 2–3 cm broad in broader, 0.5–10 mm in narrower portions; they are erect or more patent with narrower or wider, more or less rounded axils respectively; toward apices they remain either simple and ligulate, or divided into lacinae, all ending in a rounded apex, being narrower than the lower portion. Margins are entire and perfectly naked in younger and sterile forms, minutely curled or crenulated in fructified frond, appearing as if fimbriated with very minute processes, or again, in very rare cases, furnished with a few proliferous lacinae.—*Cystocarps* are hemispherical tubercles, prominent on one surface, being situated on both surfaces of frond, crowned with mostly two short bluntish prominences. They are formed in some forms, exclusively in intramarginal portions, some being situated in marginal processes, in others on the surface of frond at the same time. *Tetraspores* densely scattered all over the frond which is either entire or curled at margin. *Color* blood-red or rosy, fading to greenish. *Substance* membranous, or thin and soft leathery, becoming thickish in older specimens.”

Hypnea cervicornis J. Ag. Sp. Alg. II, p. 451; Id. Epicr. p. 564; De
Toni Syll. Alg. IV, p. 480.—*H. spinella* Kg. Tab. Phyc. XVIII, t. 26.

Fronds forming large, loosely intricated, globular or slightly depressed mass, attaching at basal branches to gravels, stones, shells etc. by disc like attachments, irregularly branched in divaricato-dichotomous manner. Branches protruding from general mass branched in similar manner, here and there with pinnate segments and densely loaded on all sides with minute or elongated, simple or branched spinose ramelli, 3-5 or 10 mm long, which taper to sharpish points from broader bases. Thicker branches measure 1.5-2.5 mm in thickness, while slender ones are very fine. Ramelli grow up into ramuli which gradually develop into branches and there is no regularity. Branches are very patent with rounded axis, often almost horizontal, making in upper portion the ramification like cervus-horns and gradually taper to a fine point. They unite to each other by disc-like attachments forming an inextricable mass, so that it is unable to disentangle branches without breaking. Frond internally consists of large, almost empty, thin-walled cells and as consequence branches become very much wrinkled when dried. Ramelli or ramuli bearing *tetraspores* swell into fusiform or ovate segments a little above the base.

Cystocarps solitary or mostly 3-5 aggregated, ovate or globular, sessile, borne on ramelli or ramuli. Color reddish purple, fading to yellowish or brick red. Substance membranaceous and soft cartilaginous, very brittle when recent; plant imperfectly adheres to paper in drying.

Hab.: growing over rocks, stones, gravels or corallines below low tide. Common along the Pacific coast from Ryukyu to Prov. Boshyu. Kuyonpo (Chosen).

On referring the present plant to this species, I was not able to see any reliable specimens but an illustration given in Kuetz. *l. c.* and references cited above.

Chondrus elatus Holmes.

Nom. Jap.: *Kotodzi-tsunomata* or *Naga-tsunomata*.

PL. CLX, Fig. 6-14.

Chondrus elatus Holms On Mar. Alg. fr. Japan, 1895, p. 252, t. IX, 1; De Toni Syll. Alg. IV, p. 182.—*Chondrus platynus* β *elongatus* Martens Preus. Exped., Tange, p. 118?

Fronde caespitose rising from callous disc, tereti-compressed, rather linear, 3-4 mm thick, ca. 15-25 cm high, many times (5-6 times) distantly dichotomous above the halfway of the whole length, with widely parted and roundish axils. Branches obtuse or bifid at apex, equally broad or slightly narrow at base, with or without short, simple or mostly once forked ramuli which arise from both margins in almost horizontal direction, sometimes solitary, sometimes seriated in some number. Segments bearing fruits become sometimes slightly torulose, but mostly remain entire.—*Cystocarps* usually formed in upper branches, slightly prominent on both surfaces, large, elliptical and ocellate. *Tetrasporic sori* forming small oval specks densely scattered over the terminal branches, immersed beneath cortex. *Color* dark purplish red with brownish tinge. *Substance* cartilaginous and the plant becomes rigid in drying.

Hab.: On rocks between tide marks. Pacific coast from Prov. Totomi to Prov. Rikuchyu.

Martens describes in his *l. c.* *Chondrus platynus* β *elongatus* get at Yokohama with the diagnosis: "fronde basi tereti, dichotoma, angusta, elongata." This I think most probably to be same as the present plant, though I do not see any specimen of it.

PL. CLXI

Gracilaria Chorda Holm.

Nom. Jap.: *Tsuru-shirano*.

PL. CLXI.

Gracilaria Chorda Holm. On Mar. Alg. fr. Japan 1895, p. 253; La Nuova Notarisia 1897, p. 23; De Toni Syll. Alg. IV, p. 454.

Fronde caespitose rising from a large circular scutate disc, elongated, 60-100 cm. long, cylindrical with more or less traceable main segment, thickened at the middle portion into the thickness of 2-2.5 mm. in diameter, attenuated below into the slender stem and tapering above into filiform apex, furnished on all sides with alternate and similarly shaped branches. Branches elongated often 60 cm. or more long, not densely arising, but scattered and strongly attenuated gradually toward the base and apex; they are mostly simple and naked, sometimes loaded with a few short and slender, filiform branchlets. Frond internally consists of large almost empty thin-walled cells, covered with sharply defined thin layer of cortex which consists of a few layers of thick-walled cells, arranged parallel to the surface. *Cystocarps* sessile, prominent, hemispherical, not crowned with beaks; nucleus simple, not lobed and there is no filament connecting pericarp and placenta. *Tetraspores* scattered among cortical layer. *Colour* deep purplish red. *Substance* soft cartilaginous; the plant becomes much collapsed and imperfectly adheres to paper in drying.

Hab.. On rocks in shallow waters protected from the open sea, one meter below low tide. Prov. Sagami, Prov. Idzu, Prov. Kii. Fruits:—spring.

Halymenia Harveyana J. Ag. .

Nom. Jap.: *Isonohana*.

PL. CLXII, Fig. 1 3.

Halymenia Harveyana J. Ag. Anal. Alg. 1892, p. 55; De Toni Syll. Alg. IV, p. 1539.—*Halymenia Floresia* (non. Ag.) Harv. Phyc. Austr. t. 214.

Some six herbarium-specimens before us, all destituting of the lower portions, the largest one about 15 cm. high. *Fronde* plano-compressed, provided with a broadly linear principal lamina or rachis, 5–7 mm. broad (in dried specimens), either simple or forked or somewhat multifid and is set on both sides with approximate or subdistant lateral branches or pinnae which are furnished with the second or third or even fourth series of lesser divisions, disposed in a similarly pinnate manner, becoming narrower in order. All branches stand on roundish axils and their apices are very

acute with ultimate divisions much acuminate like teeth. Margin in some specimens is quite flat and entire or little provided with teeth, in others slightly serrated. In ours, the surface is mostly free from proliferations, but in one or two specimens a few, small, short, denticular processes are emitted. The form, ramification and size of fronds are much varied according to the specimens. No fruit seen in ours. The interior of frond is less densely traversed by filaments and is somewhat tubular, externally covered by a cortical layer consisting of 5-6 rows of cells. *Colour* a bright pinkish red, soon discharged in fresh water in decomposition, as it is seen from the decaying of colour into greenish-yellow as well as from red coloring of paper on which the frond is mounted. *Substance* thin and very soft gelatinous. In drying the plant most closely adheres to paper.

Hab.: Ryukyu Isl. (Okinawa), Bo (Prov. Satsuma).

On comparing with *Halymenia formosa* Harv. the present plant is much thinner in substance, much lighter in color, much more dentate rather than spinose and ramification is more pinnate.

Microcladia dentata Okam. sp. nov.

Nom. Jap.: *Kosuji-sacda*.

PL. CLXII, Fig. 4-9.

Diagn.: Fronds narrow-linear, compressed, membranous, disticho-alternately pinnate with widely parted, slightly flexuose: branches standing on round axils, arranged in paniculate-cymose manner, and loaded with alternate sharpish ramuli which have ramelli or lacinulae appearing like minute teeth. Tetraspores in double rows in ramuli.

Hab.: Shimabara (Prov. Hizen), Kagoshima (Prov. Satsuma).

Descrip.: Fronds narrow-linear, ancipito-compressed, membranous, alternately pinnate, erect or ascending from decumbent lower portions, where the plant emits monosiphonous jointed root-fibres from the under-surface. Branches distichous with patent and rounded axils, slightly flexuose, arranged in paniculato-corymbose manner with longer ones below and becoming gradually shorter upward. They are

loaded in their whole length with alternate branchlets which have alternately arising ramelli or lacinulae. Lacinulae appear like marginal teeth, remain simple, bifid or trifid and end in sharpish apices. The shorter lacinulae or ramelli appear like teeth as just spoken of, but when elongated they develop into ramuli which have teeth-like ramelli or lacinulae in turn. Plant attains 4-6 cm. in height with the breadth of about 0.3-0.7 mm. in segments. *Tetraspores* regularly arranged in double rows in ramuli, roundish. *Colour* red. *Substance* membranous and the plant does not adhere to paper in drying.

A close affinity of the present plant with *Microcladia elegans* Okam. (Vol. I, p. 1-4, PL. I, fig. 1-10) is beyond any doubt. The difference between the two related plants is found in the absence of dichotomo-flabellate pinnae in the present plant.

Chnoospora obtusangula (Harv.) Sond.

Nom. Jap.: *Mura-chidori*.

PL. CLXIV, Fig. 1-9.

Chnoospora obtusangula (Harv.) Sond. Alg. trop. Austr., p. 45; De Toni Syll. Alg. III, p. 465; Id. Phyc. Jap. Nov., 1895, p. 54.—*Dictyota obtusangula* Harv. Char. new Alg., 1859, p. 329, no. 14; Kuetz. Tab. Phyc. IX, t. 28, f. 2.

Known only in herbarium-forms. *Fronde*s narrow linear, thick and sacculent as it is seen from the restored states in reimmersing dried fronds, elongated, very distantly forked below, divaricately dichotomous with very wide and round axils, becoming denser and more irregularly dichotomous toward apices with short and slender segments.

I have some young and small depressed intricately fronds

10 11 12

みらちどり Fig. 1-9.
多葉スズ Fig. 10-12

collected at Ogasawara-jima, which have basal segments united to each other by hair-like roots emitted from epidermal cells. From structure of the frond and its habit I think the Ogasawara-specimens to be young fronds of the present plant; and if this judgement does not fail the basal portion of the present plant should be said to be the intricate and coalesced mass. In one of specimens from Ryukyu, I found fruits appearing like the same construction as those of *Chnoospora fastigata* J. Ag. illustrated by Barton in Journ. Linn. Soc. Bot. Vol. 13, p. 507-508 (1897-98) Pl. 28, fig. 4-5. Colour dull yellowish brown in dried state. Substance membranous in dried frond, and the plant does not adhere to paper in drying.

PL. CLXIV, fig. 1-9. fig. 1: frond of *Chnoospora obtusangula* (Harv.) Sond., $\frac{1}{4}$.—Fig. 2: sterile frond from Ogasawara-jima, $\frac{1}{4}$.—Fig. 3: cross-section of the frond illustrated in fig. 2, $\frac{1}{12}$.—Fig. 4: surface view of frond from Ryukyu, $\frac{220}{1}$.—Fig. 5: apical portion of the same, $\frac{48}{1}$.—Fig. 6: cross-section of frond, $\frac{48}{1}$.—Fig. 7: portion of the cross-section, $\frac{353}{1}$.—Fig. 8: portion of longitudinal section seen from the inner side, $\frac{353}{1}$.—Fig. 9: fruits in fronds from Ryukyu, $\frac{336}{1}$.

Coilodesme Cystoseirae (Rupr.) Setch. and Gard.

Nom. Jap.: *Yezofukuro*.

PL. CLXIV, Fig. 10-13.

Coil. Cystoseirae (Rupr.) Setch. and Gard. Alg. N. W.
Am. p. 241; Setch. Alg. nov. et min. cognitae I (Calif. Publ.)
Bot., Vol. 4, n. 14, 1912, p. 232; Yendo Notes on Alg. new
to Jap. (Bot. Mag. Tokyo, Vol. XXIII, n. 270, p. 122).—
Asperococcus Cystoseirae Rupr. Tange d. och. Meer. p. 370.
—*Coilodesme linearis* Saund. Harr. Alask. Exped. Alg. p. 421,
Pl. 48.—*Encoelium?* *Cystoseirae* Rupr. in Kuetz. Tab. Phyc.
Bd. IX, p. 4, tab. 6, f. 4; De Toni Syll. Alg. III, p. 496.

Fronde simple narrow-linear when young, bullato-cylindrical at beginning, but more or less collapse later, thin-walled and wrinkled, obtuse at apex or often splitted, with a short abrupt stem, light yellowish brown, 10-15 cm. long, 5-13 mm. broad, firmly adhering to paper in drying.

Hab.: Epiphytic on the frond of *Cystophyllum hakodatense* Yendo. Akkeshi.

Our plants in an external appearance somewhat resemble *Coilodesme Californica* (Rupr.) Kjellm. (Syn. *C. amplissima* Setch., n. sp.) illustrated in Saunders Phycological Memoirs p. 160, Pl. XXIX, fig. 1-3, but it differs from ours by having young obovato-oblong fronds as illustrated in Saunders *l.c.* instead of linear or cylindrical. Judging from Setchell's Analytical Key of the species of the genus (Alg. nov. et min. cogn. 1) and from its point of distribution, habits etc. I think the present plant may be safely referred to this species.

Ulva conglobata Kjellm. and f. *densa* Kjellm.

Nom. Jap.: *Botan-acrosa*.

PL. CLXV, Fig. 1-10.

Ulva conglobata Kjellm. Marina Chlorophyc. fr. Japan 1897, p. 10, tab. 2, f. 1-7, tab. 3, f. 9-14.

Fronde minor, usually 2-4 cm. high, 100-125 μ thick at the basal portion which becomes subcartilaginous later, upper portion thin and membranous, 30-50 μ thick, bright green, not mucose, with very short stipe, caespitose and expanding in almost circular mass, branching or parting from base into many lobes which expand to oval or oblong segments, often much dilated, more or less decomposed with lobules or lacinulae and very much undulato-crisped, cucullated, and not pertused with foramens; cells in the basal portion prismatic and lumen of cells $1\frac{1}{2}$ -2 times high as thick in transverse section with thickened outer walls, those of upper and marginal portions subequal to or little higher than broad; fertile cells slightly higher than the vegetative cells of that portion, afterward becoming a little prominent with aperture.

f. *densa* Kjellm. Minor, forming globular mass of about 1 cm. diameter, rather thick membranous.

Hab.: On rocks near high tide. Prov. Satsuma, Amakusa-Isl., Goto Isl., Shiwono-misaki, Prov. Sagami and Boshyu.

Mr. Yendo is of opinion that the present species is same as *U. rigida* Ag. (Yendo: Notes on Algae new to Japan, V,

11 *Cladophora alba* (Ch. Br.) Falkenb. しまだじあ Fig. 1-13.

Heterosiphonia pulchra (Okam.) Falkenb.

Nom. Jap.: *Shima-dasya*.

PL. CLXVI, Fig. 1-13.

Heterosiphonia pulchra (Okam.) Falkenb. Rhodom. p. 647.—*Dasya pulchra* Okam. Contr. to the Knowl. of the Mar. Alg. of Jap. II. (Bot. Mag. Tokyo, Vol. X, no. III) 1896, p. 34, Pl. III, fig. 14-16.—*Heterosiphonia notensis* Okam. *l. c.* p. 34, Pl. III, fig. 17-21.

Frond epiphytic, 3-6 cm. high, filiform, 200-300 μ thick, not much attenuated above, articulated throughout, 4-siphonous, tereti-compressed, 3-4 times pinnate in a full-grown plant, thoroughly alternate and distichous, with more or less percurrent stem, branching into some main divisions. Basal portion of frond comes in contact with the substratum by means of basal pinnae which are transformed to rook-like fibres. Main branches mostly twice pinnate, very patent, weak and longer below, gradually becoming erecto-patent and shorter above and thus assuming the pyramidal outline. Branches of every order patent, slightly flexuose, elegantly furnished with short pinnae of subequal length and take linear outline, but in some, upper branches become decompound and take subcorymbose appearance. Pinnae 1-1.5 mm. long, standing at every 3rd or 4th (or 2nd) node, patent, dichotomous or dichotomopinnate, branching and bearing stichidia along the inside of pinnae; some of pinnae often grow up into branches. The number of articulations intercepted by branches and pinnae varies from 2-5, rarely more; but 2, 3 or 4 are common in proportion. Pinnulae subulate, monosiphonous for the most part, some with a few basal cells polysiphonous

rising from every second node, some times forked. Articulations half as long as or subequal to the diameter in basal portion, little longer in the median portion of branch, again becoming subequal in pinnulae, and 3 cells are seen in surface view. Stichidia lanceolate at first, linear-lanceolate or oblong and apiculate when fully grown, compressed, with an one-cell-long polysiphonous pedicel, coated with transversely arranged rectangular cells. Cystocarps urn-shaped, sessile, sitting on the thick and polysiphonous axis of pinnae. Colour pinkish red. Plant soft and flaccid and closely adheres to paper in drying.

Hab.: On several algae in the sublitoral zone. Kyushu to Hakodate; Japan Sea. Fruits: spring—summer.

Since the publication of the present plant and very closely related species, *H. notoensis*, as new to science, I have collected many specimens of both species from several localities and have found that there are many forms which are not easy to distinguish one from the other. In the typical form of *H. pulchra* upper and lower pinnae upon one and the same branch are almost equal in length, while in *H. notoensis* upper pinnae are decomposed and consequently branch assumes sub-corymbose outline. But as those characters are not definite, there being many irregularities in both species, I came to consider that *H. notoensis* is nothing but a robust form of *H. pulchra* and better to unite the both plants under one species.

Heterosiphonia japonica Yendo.

Nom. Jap.: *Isohagi*.

Pl. CLXVII.

Heterosiphonia japonica Yendo Nov. Alg. Jap. Decas I-III, no. 23 (Bot. Mag. Tokyo, Vol. 34, n. 397, 1920, p. 8).—*H. densa* Okam. n. sp. mscr.

Frond erect, rising from a small scutate disc, with a more or less distinct main stem, or often divided into many main divisions from near base, 10-20 cm. high, 0.5-0.8 mm. thick at thicker portion, 3-4 times pinnately branched in a distichous manner. Branches of every order arise from every node in an alternate manner, more or less slightly flexuose, more so in slenderer portions. Dorso-ventral character is well shown in the arrangement of pinnae (*i.e.* branches having definite growth), which arise on the dorsal side of branch and are directed toward the apex of the segment bearing them (Fig. 2). Pinnae patent, sometimes quite simple, 1.5-3 mm. long, but more often once or twice forked or dichotomo-pinnately branched with parted lacinae, either monosiphonous

13 7 8 1 12 2 3 4 5 6 9 4 3 japonica Tendo. いそはぎ

throughout or polysiphonous at base for a short distance, pointed at apex, sometimes branched with finger-like ramuli at apical portion (Fig. 13); some of pinnae develop into branches afterward. Branches are more or less corticated except very young portion near apex; the cortication begins as rhizoids from pericentral cells, and afterward thickly covers the 4 or 5 pericentral cells. In surface-view of thicker branches cortical cells are linear and longitudinally arranged. Length of the articulations subequal to or one half to twice as long as the diameter.—*Stichidia* lanceolate, provided with a monosiphonous pedicel, and arise either from monosiphonous or polysiphonous base of pinnae or pinnulae, often 2 or 3 aggregated. Cystocarps globular or ovate shortly pedicelled and a little prominent at apex. Colour pinkish red. Substance soft and closely adheres to paper in drying.

Hab.: Washed ashore; Iyo, Rikuzen, Yechigo.

All the species of this genus hithertoknown have branches arising generally from every second node, never from every node, as in the present plant.

Pl. CLXVII. Fig. 1: frond of *Heterosiphonia japonica* Yendo, $\frac{1}{1}$.—Fig. 2: portion of branch (having 5 pericentral cells), showing pinnae arising from the dorsal side of branch, the beginning of rhizoidal cortication, and stichidia arising from monosiphonous pinnae, $\frac{48}{1}$.—Fig. 3-5: cross-sections of different parts of branches of different plants, $\frac{48}{1}$, $\frac{34}{1}$, $\frac{15}{1}$, respectively.—Fig. 6: rhizoidal cells on the surface of main branches on the lower portion of frond, $\frac{200}{1}$.—Fig. 7: growing portion of branch showing sympodial growth of frond: *a*, apical cell, $\frac{353}{1}$.—Fig. 8: cystocarpic branch having 4 pericentral cells; *a*, *b*, forked and monosiphonous pinnae; *c*, branch of indefinite growth, forked and polysiphonous at base. $\frac{34}{1}$.—Fig. 9: polysiphonous portion of *c* in

Delesseria crassifolia Rupr.

Nom. Jap.: *Konohanori*.

PL. CLXVIII.

Delesseria crassifolia Rupr. Alg. Ochot. p. 232; De Toni Syll. Alg. IV, p. 706.—Saunders Alg. of the Expedit., 1901, p. 201.—Farlow Notes on Arctic Algae, 1886, p. 473.—Setchell and Gardner Alg. of New America, p. 322.

Fronde erect, rising primarily from a thin scutate disc which soon lobes into fibrous rhizines as the plant grows in age, 40 cm. high or more, with a thick subcompressed stem (some measures 0.5 cm. in diam. at base in the fresh state), and decomposed by proliferations. Proliferations are produced from the midrib and veins on both surfaces. Frond in its early state of growth is a simple oblong veins or obovato-cuneate leaf which becomes lacerated laterally along the veins and proliferates similar-shaped leaves as just spoken above. Membranous portion of the primary leaf becomes gradually wasted and thus the midrib is transformed into stem and veins into branches. In this way the plant is more and more decomposed. Leaves are very variable in size and shape, some ovate or oblong, others obovate or elliptical, still others sublanceolate with obtuse apex. Some have the length of 15-16 cm. by breadth of 10, others 3 by 2; but 10-12 cm. by 3-5 is more usual. Midrib and veins are usually prominent and veinlets are also more or less evident, but in some they are very weakly provided. Veins are in most cases widely parted forming an angle more than 45° with the midrib,

Delesseria crassifolia Rupr
このけのり

some wider, others narrower. Margin entire, or slightly wavy. Surface flat or undulated. Leaves are more usually radially lacerated as if eroded. *Tetraspores* are unknown to me. *Cystocarps* almost globular, slightly prominent at apex, with short pedicels, produced on veins or veinlets as well as on intercostal portions of both surfaces. *Colour* deep purplish red. *Substance* thick membranous, rather soft-leathery, and plant in age does not adhere to paper in drying.

Hab.: Often washed ashore; east and west coasts of Kabafuto. East coast of Hokkaido, N.E. coast of Chosen.

Cladophoropsis fasciculatus (Kjellm.) Borges.

Nom. Jap.: *Midorige*,

Pl. CLXIV, Fig. 1-7.

Cladophoropsis fasciculatus (Kjellm.) Börg. Contr. a la Connais. du Genre Siphonocladus Schmitz, 1905, p. 288.—*Siphonocladus fasciculatus* Kjellm. Mar. Chlorophy. fran Japan, 1897, p. 36, tab. 7, fig. 10-17.—*Cladophoropsis coriacea* Yendo, Nov. Alg. Jap. Decas I-III, no. 1 (Bot. Mag. Tokyo. Vol. XXXIV, 1920, n. 397, p. 1.)

Fronds filiform caespitose, forming pulvinato-globose or vaguely expanded mass, 2-3 cm. high, composed of densely compacted erect filaments. Filaments profusely branching in sympodial succession or arising subfasciculately, having branches and branchlets standing in alternate, opposite or often subsecund manner. They are very patent and more or less curved, and upper ramuli which are mostly longer than the lower ones often emit root fibres by which filaments are kept together; septa are here and there seen in upper ramuli, but not at the place where branches arise. Wall of filaments 10-20 μ thick (sometimes 30 μ) in thicker portion of frond, but in thinner ones, 3-14 μ . Diameter of filaments measures 125-350 μ . *Substance* rigid when fresh, in drying coarse

to touch, and the plant does not adhere to paper, but in reimmersing in the water filaments become very soft. Colour bluish-green.

Hab.: On rocks near high tide. Hyuga, Hizen, Tosa, Boshyu.

In identifying my plant for Kjellman's *Siphonocladus fasciculatus* I have not seen the authentic specimen, but from the illustrations and descriptions given by him I think I am justified in doing so. The locality, Yokohama, where he obtained his material is very near to Boshyu where our material was collected. Prof. Yendo recently described a new species, *Cl. coriacea*, which he remarks as easily distinguishable from other related species by the thickness of the wall (he measures 10-40 μ). His specimens were collected at Provs. Boshyu and Sagami, Goto Island, etc. I also collected the material from the similar localities mentioned by him, and though I have not seen his specimen, I have in my herbarium one collected by him at Boshyu in early date. On examining my material which has been formerly collected by him at Boshyu, some have thick wall measuring 33 μ , but the thickness is not uniform all over the frond, 10-20 being more common, and thicker part is limited to the lower older portion or root-like filaments; and the most part of the filaments whose basal portion has thick wall remain thin. I have measured the thickness of 4.6-14 μ in the material from southern parts as Hyuga and Tosa (equally warm places as Goto Island); in the warmer part thin-walled frond seems to be more common. Provs. Boshyu and Sagami (including Yokohama) are most provably the northernmost limit of the distribution of this plant.

Pl. CLXIX, Fig. 1-7. Fig. 1: portion of the expanded mass of *Cladophoropsis fasciculatus* (Kjellm.) Börg. from Hyuga in nat. state and size.—Fig. 2: frond (from Boshyu) isolated, $\frac{1}{2}$.—Fig. 3: frond (from Hyuga) isolated, $\frac{1}{2}$.; *r*, root.—Fig. 4: lower rooting filaments (from Hyuga),

$\frac{2.2}{1}$.—Fig. 5: basal filament (from Boshyu), $\frac{1.6}{1}$.—Fig. 6: portion of frond (from Hyuga), ca. $\frac{1.0}{1}$.—Fig. 7: the same, $\frac{1}{2}$; thickness of filaments measures 320-350 μ and 260 μ at base; r , root.

Ulva pertusa Kjellm.

Nom. Jap.: *Aua-aosa* or *aosa*.

PL. CLXIX, Fig. 8; Pl. CLXX.

Ulva pertusa Kjellm. Mar. Chlorophy. fr. Japan 1897, p. 4, tab. I, fig. 1-5, tab. 3, fig. 1-8. For synonyms vid Kjellm. *l.c.*

Frond solitary or a few tufted rising from a callous disc, 10-30 cm. high or more, almost stemless, lower portion very thick measuring 472 μ just above the holdfast (Fig. 15) where the surface is concentrically wrinkled, soon becoming thinner above, measuring at least 125 μ in thickness, subcoriaceous, and thin membranaceous at margin, 40-50 μ

thick. Frond is very variable in shape being oval, elliptical, sub lanceo- late or suborbicular etc., rarely undivided, usually more or less irregularly lobed and lacerated, sometimes folded or roughly wrinkled, undulated, and entire or repando-dentate at margin; surface usually perforated by larger or smaller roundish or irregularly shaped foramens which often become confluent. Cells in the lower portion of membrane vertically elongated in long prismatic form, 2-3 times high as broad in cross-section with rather thick outer wall; in marginal portion cells become shorter and subcubical, being almost equally high as broad or a little surpassing it. When fructified, the margin of frond is transformed into broadly linear rim of olive-yellow coloured sori; fertile cells are a little higher than adult vegetative cells and open by teat-like pores. *Colour* when young beautiful yellowish-green, when adult becoming bluish-green and opaque. *Substance* rather rigid when fresh, and the plant does not adhere to paper in drying.

Hab.: At first the plant grows on shells, pebbles, rocks, twigs etc. in littoral zone, afterward often becoming free and continues to grow even in that state. Very common along both coasts of this country as far as Kurile Islands. Chosen, Taiwan and Ogasawarajima. Swarmspores: late in spring.

I was not able to see the conjugation of the two-ciliated swarmspores of this plant in the vicinity of the Tokyo Bay, and the zoospores with four cilia have not yet been observed.

木下しり Fig. 6-12

Thorea ramosissima Bory.

Nom. Jap.: *Chisuji-nori*.

PL. CLXXI, Fig. 1-5.

Thorea ramosissima Bory ; Engl. u. Prantl, Die nat.-Pflanzenfam. p. 324, fig. 198.—Klg. Phyc. gener. p. 326, t. 16, f. 1 ; Id. Sp. Alg. p. 534 ; Id. Tab. Phyc. VII, t. 90, f. II.—Moeb. in Ber. d. deutsch. bot. Ges.; IX. (1891), p. 338, t. XXII, f. 7-14.—W. Schmidle, Unters. ii. Thorea ramosissima Bory (Hedwigia Band XXXV, 1896)—De Toni Syll. Alg. III, p. 587, IV, p. 33.

Fronds filiform, very soft, slimy and flaccid, abundantly branched on all sides in twice pinnate manner from the base, with longer and shorter branches mixed, 250-300 μ thick, gradually tapering upward and the plant attains 10-45 cm. or more in length. Hair measures 500-700 μ in length, and 56 μ in thickness, and the articulations 2-3 times long as broad or more ; the thickness of fusiform part of basal portion of hair measures about 11 μ . *Colour* dark violet. Plant closely adheres to paper in drying.

Hab. : Freshwater alga growing on pebbles in quickly running rivulets. Prov. Ohsumi and Ryukyu. Dec.-March.

Bangia fusco-purpurea (Dillw.) Lyngb.¹⁾

Nom. Jap: *Ushike-nori*.

PL. CLXXI, Fig. 6-12.

Bangia fusco-purpurea (Dillw.) Lyngb. Hydrophyt. Dan. p. 83, t. XXIV, c; Berthold, Die Bangiaceen des Golfes von Neapel, 1882, f. 12-14; Kolderup-Rosenvinge Mar. Alg. of Denmark, I, p. 56.

1) Following the views of Kolderup-Rosenvinge and most of the marine algologists I put the plant under the present specific name.

Froths forming dense, expanded tufts, 3-15 cm. long, dark purplish brown to reddish-yellow or yellowish, with more or less violet or blue-greenish nuance. Filaments very soft and flaccid, with varnish-like lustre when dried, simple, straight or crooked, 20-35 μ thick in sterile portion, consisting of single row of cells, in fructified portion composed of many rows or almost parenchymatically disposed cells (often 150 μ in diam.) having different thickness according to ages. Articulations $1\frac{1}{2}$ - $\frac{3}{4}$ times long as diam., mostly half times long. In drying the plant firmly adheres to paper.

Hab.: On rocks, stones, woods etc. near high tide. Very common along the both coasts of this country.

Pl. CLXXI, Fig. 6-12. Fig. 6: froths of *Bangia fusco-purpurea* (Dillw.) Lyngb., $\frac{1}{1}$.—Fig. 7-10: different parts of one and the same filament, $\frac{300}{1}$; 7: basal rooting portion; 8: sterile portion a little above the base; 9: fertile portion more above than in the fig. 8 with cells radially divided as shown in fig. 12; 10: uppermost portion with fully grown carpospores.—Fig. 11: cross-section of filament as shown in fig. 8, $\frac{300}{1}$.—fig. 12: cross-section of filament with cells radially divided as shown in fig. 9, $\frac{300}{1}$. (The printed colour of *Bangia* is much different from the normal, though in some individuals dark violet color is sometimes observed.)

Erythrophyllum Gmelini (Grun.) Yendo.

Nom.-Jap.: *Yezo-tosaka*.

PL. CLXXII.

Erythrophyllum Gmelini (Grun.) Yendo, Bot. Mag. Tokyo, Vol. XXIX, n. 345, 1915, p. 230, fig. 1-3.—*Callymenia Gmelini* Grunow;

Erythrophyllum Gmelini (Grun) Yendo
 えぞときか

Setch. and Gardn. Alg. of N. W. Amer. p. 307.—*Fucus palmetta*, Gmelin, Hist. Fucorum, Taf. XXIII.

Fronde membranaceous, irregularly parted into di-polychotomous or subpalmately lobed blades, which again may become lacerated into irregularly shaped minor segments ending in blunt apices, with entire or minutely spinulated and undulato-sinuated margins. The basal part of a blade often becomes more or less thickened as if provided with evanescent midrib, but no sort of rib or vein is to be found, and, by gradually wasting away of the membrane in the lower portion of frond the plant often appears to have more or less elongated ancipito-compressed stem which often measures 3-10 cm. in length. Thus the frond is sometimes irregularly lobed simple leaf, sometimes provided with branches, each of which terminates with an irregularly clefted or longitudinally splitted blades having fan-shaped, cordate or reniform outline, and they are spread in one plane with some lobes overlapping to each other. Frond consists of 3 layers; epidermal, cortical and medullary. The epidermal layer consists of a single layer of vertically arranged small cells; cortical of a few layers of almost globular cells. The medullary layer which forms the main portion of the thickness of frond consists of large and elongated elliptical cells, accompanied by subglobular ones, which are longitudinally arranged in rather loose aggregation without any definite order, as if composed of anastomosing hyphal cells. A peculiarity in the structure of the present plant is the presence of a yellowish homogeneous hyaline substance in some of the medullary cells; those containing it are more elongated than the others, in most cases having rod-like or fusiform shape of irregular outline, and have no definite position. Colour of the peculiar contents is mostly yellowish, but sometimes milky or colourless. *Fruits* unknown. *Colour* purplish-

red. *Substance* membranaceous and the plant adheres to paper in drying.

Hab.: Often washed ashore; common along the east coast of Hokkaido, Kurile.

Pl. CLXXII. Fig. 1-3: two different fronds of *Erythrophyllum Gmelini* (Grun.) Yendo, $\frac{1}{4}$.—Fig. 3: outline of cross-section of the lower thickened portion of frond, $\frac{3}{4}$.—Fig. 4: almost half of a cross section of blade cut through the upper portion of midrib-like thickening, to show that the cells are filamentous and dense, $\frac{17.5}{1}$.—Fig. 5: cross-section of the upper portion of blade, $\frac{17.5}{1}$.—Fig. 6: content of so-called peculiar cell, partly granular, partly homogenous and hyaline, $\frac{17.5}{1}$.—Fig. 7: longitudinal section of a younger and thinner blade showing that cells are shorter or oblong than in the older portion, $\frac{17.5}{1}$.—Fig. 8: portion of longitudinal section of blade showing the connection of the peculiar cell (illustrated in deeper colour) with cortical cells, $\frac{17.5}{1}$.

Scinaia Cottonii Setch.

Nem. Jap.: *Hira-fusanori*.

PL. CLXXIII, Fig. 1-7.

Scinaia Cottonii Setchell, The *Scinaia* Assemblage, 1914, p. 103, Pl. II, fig. 24.—*Scinaia complanata* Cotton, in Kew Bulletin, no. 7, p. 260, 1907 (as to Japanese plant only).

Plant solitary or a few tufted, rising from a small scutate disc, purplish-red, 9-12 cm. high or more, 5-7 times dichotomous, abruptly tapering

K Okam, del

Cladophora settonii Setch. ひらふさのり Fig. 1-7.
Tylocladia nakamurae Okam. なみいはたけ Fig. 8-15.

below to a short cylindrical stem, with a little or widely patent, more or less acute axils. Branches slightly attenuated below, compressed, not evenly flat but transversely wrinkled in short distances making slightly wavy elevations like ridges, which are sometimes somewhat reticulated; not constricted anywhere, and thickened on both margins, 3-10 mm. broad; axial filaments not visible; apex bifid. Epidermis consists of a layer of large, colourless cells which are rectangular-oblong, 27-30 by 40-46 μ with tops slightly arched; hypodermal layer consists of rather loosely packed coloured globular cells. *Cystocarps* scattered, with some tendency toward intramarginal aggregation, depresso-globular, immersed in the frond, slightly prominent with an opening above; nucleus surrounded by the tissue of parenchymatic cells which are in connection with inner filaments of frond; spore-filaments densely packed whose terminal articulations mature to spores. *Colour* beautiful purplish-red. *Substance* succulent, membranaceous when dried and firmly adheres to paper in drying.

Hab.: In deeper waters. Sagami, Boshyu, Enoura (Saida).

The transverse wrinkles are very peculiar to the present plant which most probably should have escaped keen eyes of Cotton and Setchell as they become often hardly visible in preparing for herbarium-specimens. *Sc. latifrons* Howe (Phyc. Stud. V, Some Mar. Alg. of Low. Calif. Mexico, 1911, p. 500, Text-fig. 1, pl. 28) I think, most probably should be the same as the present plant; for, transverse wrinkles are visible in his illustrations (*l.c.* p. 501 text-fig. 1 and better, Pl. 28). They should not be mere wrinkles resulting from the process of drying, but elevated ridges in fresh state as the surface of frond in our herbarium-specimens shows the similar appearance as it is seen in his illustrations. Cotton (Kew Bull., no. 7, p. 260, 1907) identifies the present plant with his *Sc. complanata*¹⁾ which he raised to the specific rank from a form of *Sc. furcellata*

1) This specimen I have seen through the kindness of Mr. Narita.

Biv., but I can not agree with him; for, in the note in Phyc. Bor. Amer. no. 836, he states that "the frond is flattened throughout, even when quite fresh" and does not mention the presence of transverse wrinkles in its fresh state. I was very strongly inclined to name the present plant as *Sc. latifrons* Howe and put *Sc. Cottonii* Setch. as its synonym, but as I have not seen any reliable specimen of *Sc. latifrons* I refrained, for the present, from doing so.

Pl. CLXXIII, Fig. 1-7. Fig. 1: cystocarpic frond of *Scinaia Cottonii* Setch. from fresh material, $\frac{1}{1}$.—Fig. 2: cortical portion of frond, $\frac{390}{1}$.—Fig. 3: longitudinal section of branch showing ridge-like wrinkles; two cystocarps are seen in the section; the ends marked with × are to be continued to each other; *a, a*, indicate the same sides of frond, $\frac{5}{1}$.—Fig. 4: cross-section of a branch showing the thickness, $\frac{5}{1}$.—Fig. 5: vertical section of a cystocarp, $\frac{91}{1}$.—Fig. 6: tissue surrounding the nucleus, magd.—Fig. 7: spore-filaments, $\frac{220}{1}$.—(All the figures except 5 and 7 were prepared from fresh materials; 5 and 7 from dried ones).

Tylopus lichenoides Okam. Sp. nov.

Nom. Jap.: *Nami-iwatake*.

PL. CLXXIII, Fig. 8-15.

Fruond repent, attached to the substratum by emitting papillae or short (3-4 mm. long), cylindrical rhizoidal processes from the under-surface, subcoriaceous-membranaceous, irregularly lobed with di-polychotomous, often slightly imbricated lobes which end in roundish apices with undulato-sinuose margins. *Cystocarps* prominent, sessile, mostly along margins of lobes,

globular, depresso-umbilicate, pertused above. *Tetraspores* very small, forming oval or irregularly roundish, flat, wart-like nemathecia which are scattered over the upper surface of frond. *Colour* dark red, becoming almost black in drying. *Substance* coriaceo-membranaceous tenaceous, becoming hard in drying and the frond does not adhere to paper.

Of *Tylotus*, only one species, *T. obtusatus* J. Ag., is hitherto-known, of which Prof. Yendo remarks that there are two forms in Harvey's type specimens (Notes on Alg. new to Jap. III, Bot. Mag. Tokyo, Vol. XXIX, no. 343, p. 110, 1915). "One is subdichotomously laciniated with the breadth of segments nearly equal for the whole length," as is well known in Phyc. Austr. Pl. 210. "Other is irregularly laciniated at the base, palmately lobed above with the segments broad and imbricated with the neighbouring ones. On the under-surface of the basal segments there are many papillose rhizoidal processes.—"Yendo *l.c.* With this, our specimens seem to resemble in some measures, as Prof. Yendo remarks, but he does not mention whether it is entirely erect or partly decumbent or wholly repent. I do not know whether our plant is same with this second form of Harvey or not, but the present plant seems decidedly to differ from the first form on which *T. obtusatus* is established, by having wholly repenting habit and rhizoidal processes. Based on these grounds I take the present plant as a new species.

Pl. CLXXIII, fig. 8-15: Fig. 8: two different forms of cystocarpic fronds of *Tylotus lichenoides* Okam.; one is seen with rhizoidal processes, $\frac{1}{4}$.—Fig. 9: portion of a nemathecium, $\frac{5}{1}$.—Fig. 10: one of slit-like spaces of the cystocarp with spores attached to the wall of the cavity, $\frac{2}{1}$.—Fig. 11: portion of frond bearing nemathecia, $\frac{8}{1}$.—Fig. 12: cortical and subcortical layers of sterile portion of frond, $\frac{2}{1}$.—Fig. 13: vertical section of a cystocarp, $\frac{9-1}{1}$.—Fig. 14: portion of a papilla-form elevation

Rhabdonia robusta J. Ag.

Nom. Jap.: *Mirin*.

PL. CLXXIV.

Rhabdonia robusta J. Ag. Sp. Alg. II. p. 355; Yendo, Notes on Alg. new to Jap. II, p. 273 (Bot. Mag. Tokyo, Vol. XXVIII, 1914, no. 333).—*Solieria australis* Harv. Phyc. Austr. pl. 149.

Fronde solitary or a few tufted rising from a small scutate disc, attenuating below into a short cylindrical stem, soon dilating above to broadly linear tereti-compressed main branches, 25-35 cm. long, 3-15 mm broad, 2-3 times thickly branched in an alternate manner. Branches cylindrical when young, inflato-tubulose, very much succulent and gelatinous in the fresh state, soon compressed above, ending in blunt or pointed apices, and vaguely narrowed here and there, with the bases of branchlets abruptly very much constricted, so that all the segments droop down as the plant is brought up above the water. *Cystocarps* immersed or little prominent, dispersed in the lesser sorts of branches. *Colour* reddish or yellowish purple, according to the age of plant. *Substance* gelatino-membranaceous, very succulent, and firmly adheres to paper in drying.

Hab.: In deeper waters; the Sagami Bay, Goto-Islands, Prov. Kishyu and Bosyu.

U. robusta J. Ag.
スリル

I have not been able to determine the plant in question only by consulting the literature mentioned above; for, it seems to me much to differ in several points with the present species. But I followed Prof. Yendo who identified this plant to the present species after careful studies of several related specimens kept in the herbaria of different countries.

Caulerpa scalpelliformis (R. Brown) Ag.

var. *denticulata* (Decsn.) Weber.

Nom. Jap.: *Kuroki-dzuta*.

PL. CLXXV.

Weber, *Mongr. des Caulerpa* p. 47; Svedelius, *Ecol. and System. Stud. of the Ceylon Species of Caulerpa*, p. 109, 1906; Reinke, *Über Caulerpa* 1899, p. 13, f. 14-15.

Fronde broadly lanceolato-linear, simple, with alternate or opposite lobes, some of which are very slightly curved upward, mostly straight, little attenuated toward apical portions where minute teeth are clearly seen. Branches are proliferated from the both surfaces. Leaves attain 10-15 cm. in height.

Hab.: The present plant is, so far as is known in this country, to grow in the shallow waters in Prov. Oki, an island in the Japan Sea.

Halymenia dilatata Zanard.

Nom. Jap.: *Fu-iri-gusa*.

PL. CLXXVI; PL. CLXXVII, Fig. 3-4.

Halymenia dilatata Zanard. Plant. Mar. Rubr. enum. p. 280, t. V, f. 1.—
J. Ag. Anal. Alg. 1892, p. 53.—*Sebdenia dilatata* (Zanard.) De Toni Syll.
Alg. IV, p. 531 (partim).

Fronde rising from a small scutate disc, with or without a short thickish stem, abruptly expanding with reniform base into a broad membrane which is mostly suborbicular or transversely expanded or sometimes broadly oblong, undulato-curved, simple or more or less lobed, attaining as much as 15-20 cm. in breadth and height. Margin entire, crenate or roughly subdentato-sinuose or fimbriated with ligulate lobules and more or less crisped, rarely proliferous from surfaces with small papillose or ligulate processes. Surface not evenly flat but roughly undulato-bullated.—*Tetraspores* scattered all over the surfaces of frond. *Cystocarps* minute dots, densely scattered all over the surface of frond. *Colour* purplish red, often variegated with irregularly shaped small patches. *Substance* gelatinoso-membranaceous and the plant firmly adheres to paper in drying except stem.

Hab.: In deep places at 3-9 fath. Ryukyu, Kyushu, Kishyu.

Structure of frond and cystocarp is that of *Halymenia*. Auxiliary cell which is rather large, oval or oblong, is formed as a branch of cortical filament and is situated at the point where some 5 or more cortical filaments converge (Pl. CLXXVII, fig. 3, *a*). Those filaments afterward

become the network surrounding the nucleus of cystocarp. De Toni puts this plant in *Sebdenia*; but I can not agree with him.

PL. CLXXVI. Fig. 1: Sterile frond of *Halymenia dilatata* Zanard., $\frac{1}{1}$.—Fig. 2: cross-section of frond, slightly magd.—Fig. 3: cortical layer of frond, $\frac{3.5.3}{1}$.—Fig. 4: tetrasporangia, $\frac{3.5.3}{1}$.

Sarcodia Montagneana (H. et H.) J. Ag.

Nom. Jap.: *Atsuba-nori*.

PL. CLXXVII, Fig. 1-2; PL. CLXXVIII, Fig. 8-11.

Sarcodia Montagneana (H. et H.) J. Ag. Sp. Alg. II, p. 623; Id. Epicr. p. 431; De Toni Syll. Alg. IV, p. 414; Yendo Notes on Alg. new to Jap. (Bot. Mag. Tokyo, Vol. XXXI, n. 363, 1917) p. 82.—*S. Ceylanica* Harv.; Kō. Tab. Phyc. XIX, t. 33, f. 1; J. Ag. Epicr. p. 431; De Toni Syll. Alg. IV, p. 415.

Plants solitary or a few tufted, rising from a scutate disc with cuneate base which often tapers into short, thickish stem, or almost stemless, expanding upward into 3-4 times dichotomous or irregularly lobed fronds, which are very variable in shape and size, some flabellate, others irregularly forked, attaining 10-20 cm. in height. Segments widely parted with round axils, some broadly linear, others widely cuneate, varying from 5-10 mm. to 4-5 cm. in breadth, with blunt, truncated, ligulate or bifid apices. Margin entire, smooth or provided in age with wart-like thicken-

ings or papillose processes, often furnished with simple ligulate or once or twice forked cuneate proliferations and in older plant frond becomes very much thickened.—*Tetraspores* scattered over the surfaces of frond. *Cystocarps* globoso-hemispherical, mostly situated along or within the margin, sometimes densely scattered all over the both surfaces. *Colour* brownish-red or yellowish. *Substance* thick membranaceous becoming almost leathery in age and the plant imperfectly adheres to paper in drying.

Hab.: Probably in deeper waters; Kii, Hachijo and Miyake Isls., Sagami, Rikuchyu.

Pl. CLXXVII, Fig. 1-2. Fig. 1: sterile frond of *Sarcodia Montagneana* (H. et H.) J. Ag., $\frac{1}{4}$.—Fig. 2: another frond bearing cystocarps, $\frac{1}{4}$.

Champia expansa Yendo.

Nom. Jap.: *Usuba-watsunagiso*.

PL. CLXXVIII, Fig. 1-7.

Champia expansa Yendo Three New Mar. Alg. from Jap. (Bot. Mag. Tokyo, Vol. XVII, 1903) p. 103, pl. III, f. 10-13.

Frond compresso-complanated, regularly dichotomous, expanding in a flabellate manner, with reniform outline, abruptly tapering below into

cuneate base, 6-10 cm. high. Segments broadly linear or cuneate, erectopatient or patent with round axils, 6-10 mm. broad concentrically zonate in short distances, bifid at apices, and proliferating from margins of adult segments.—*Cystocarps* ovoid sessile on the surface of frond. *Colour* purplish-red. *Substance* membranaceous and the plant firmly adheres to paper in drying.

Hab.: On rocks about 8 fathoms deep below the tide marks at Misaki (K. Imamura); Choshi, Wagu.

Pl. CLXXVIII, Fig. 1-7. Fig. 1: frond of *Champia expansa* Yendo, $\frac{1}{1}$.—Fig. 2: cross-section of frond, $\frac{220}{1}$.—Fig. 3: surface view of frond, $\frac{220}{1}$.—Fig. 4: longitudinal section of frond through a dissepiment, $\frac{220}{1}$.—Fig. 5: portion of frond bearing cystocarps, $\frac{1}{1}$.—Fig. 6: cystocarp, $\frac{22}{1}$.—Fig. 7: vertical section of cystocarp, $\frac{48}{1}$.

Ceramium tenerrimum (Mart.) Okam.

Nom. Jap.: *Ke-igisu*.

Pl. CLXXIX, Fig. 1-7.

Hormoceras tenerrimum Mart. Tange Preuss. Exped. nach Ost-Asien p. 146, t. VIII, f. 2.—*Hormoceras flavicidum* (non Harv.) Sur. Alg. Jap. Mus. bot. Lugd.-Bat. 1870, p. 28, Tab. XIII.—*Ceramium gracillimum* Griff. et Harv.; De Toni Syll. Alg. IV, p. 1483, (partim); Okam. Nippon Soruimeii (2nd. edit.) p. 98; Okam. Alg. Jap. Exsic., fasc. I, n. 28.

Fronde densely caespitose, very fine and capillary, 60-80 μ thick, very flaccid, deliquescently dichotomo-fastigiate, forming almost globular mass,

Desmodium sinense Maxim. けいぎす F₁ 5 1-7
Desmodium perfoliatum Maxim. はりいきす F₁ 5 16

distantly dichotomous below, gradually becoming nearer above, strongly forcipated inward at apices, sometimes emitting short lateral ramuli and often root-fibres at geniculus. The articulations are 5-10 times as long as diameter, interstices pellucid, and with cells round the geniculus slightly prominent in the lower portion. Cortical cells at geniculus are sometimes small and numerous, sometimes larger and less numerous. — In one of the dried specimens I have seen *tetraspores*, 2-3 of which are verticillately arranged on one side and not much prominent, roundish and tripartite. *Cystocarps* unknown. *Colour* light pinkish red, often almost colorless. *Substance* soft and the plant closely adheres to paper in drying.

Hab.: Mostly entangled on *Sargassum* in calm places between tide-marks near high tide. Common along the both coasts of Honshyu and Kyushu; Fusan.

Hitherto I have passed in calling the present plant in the name of *Ceramium gracillimum* Griff. and Harv. after De Toni *l.c.* But on making study by comparing with a specimen labelled *C. gracillimum* collected and determined by A. D. Cotton at Bovisand in 13, 9, 1905 (which is kept in the herbarium of Tokyo Imp. Univ.), I have found that our plant is quite different. *C. gracillimum* has dark reddish-brown colour, more erect apices, and more regularly alternate ramuli which are not widely spread out but rather standing nearer to one another. Moreover its filaments are much thicker than in the present plant which is capillary-fine and it has more or less traceable main stem or main branches.

Pl. CLXXIX, Fig. 1-7. Fig. 1: small mass of *Ceramium tenerrimum* (Mart.) Okam., $\frac{1}{4}$.—Fig. 2: portion of frond, $\frac{22}{1}$.—Fig. 3: lower articulations, $\frac{83}{1}$.—Fig. 4: apical portions of ramuli shooting forth colourless

hairs, $\frac{220}{1}$.—Fig. 5: cortical cells at geniculus, $\frac{220}{1}$.—Fig. 6: root-fibre, $\frac{220}{1}$.—Fig. 7: tetraspores, $\frac{80}{1}$.

Ceramium paniculatum Okam.

Nom. Jap: *Hari-igisu*.

PL. CLXXIX, Fig. 8-16.

C. paniculatum Okam. Contr. Knowl. of the Mar. Alg. of Jap. II (Bot. Mag. Tokyo, Vol. X, 1896, no. 111), p. 36, pl. III, f. 22-23; Okam. Alg. Jap. Exsic. n. 2.

Fronds densely tufted, forming subglobose mass, capillary, ca. 3 cm. high, 130-200 μ thick, subdichotomo-alternately decomposed, shooting forth lesser sorts of branches in every direction. The basal portion of frond lying on substratum emits from nodes monosiphonous root-fibres which are mostly simple or distantly branched, ending in a blunt apex or expanding into a small conical disc. Branches short, patent, often almost horizontal, of subequal length for the most part, becoming shorter above with short similarly arranged ramuli. The entire ramification is thus a panicle. Ramuli very patent, armed with a subulate, 2-4 celled, coloured spine at each node longitudinally seriated along the external side; the lower ones often slightly recurved, some forcipated at apex, others simple and straight; the upper ones often unequally forcipated and a little recurved at extremity, becoming very patent afterwards. Articulations little shorter as the diameter in the basal portion of frond, $1\frac{1}{2}$ - $2\frac{1}{2}$ times long in the median portion, becoming shorter above. Node corticated and subequal, not being prominent, leaving interstices hyaline.—

Elymus setosus Steud. 毛 雀 麥

Tetraspores typically verticillate around the node of ramuli in a single row, prominent, slightly bulging out from the cortical layer and bracteated by cortical cells, and enclosed in a hyaline membrane, roundish, triangularly or somewhat cruciately divided. They are often seriated in a longitudinal row, here along the external, there along the internal side or along the both sides at the same time. *Cystocarps* globular, formed on the upper portion of branch and imperfectly bracteated by a few ramuli. *Colour* light pinkish-red. *Substance* soft and flaccid, and the plant adheres to paper in drying.

Hab.: On various algae between tide-marks near high tide; common along the Pacific coast from Kyushu to Hakodate.

A distinct species belonging to the section *Ciliata* J. Ag. standing in the vicinity of *C. acanthotum* Carm.

Pl. CLXXIX, Fig. 8-16.—Fig. 8: fronds of *Ceramium paniculatum* Okam. growing on *Corallina*, $\frac{1}{1}$.—Fig. 9: portion of frond, $\frac{3}{1}$.—Fig. 10: lower articulations, $\frac{83}{1}$.—Fig. 11: root fibres, $\frac{83}{1}$.—Fig. 12: apices of ramuli, $\frac{152}{1}$.—Fig. 13: branch bearing tetraspores, $\frac{50}{1}$.—Fig. 14: cystocarps, $\frac{80}{1}$.—Fig. 15-16: tetraspores, $\frac{220}{1}$.

Dilsea edulis Stackhouse.

Nom. Jap.: *Akaba*.

PL. CLXXX.

Dilsea edulis Stackh.; Yendo Notes on Alg. new to Jap. I, (Bot. Mag. Tokyo, Vol. XXIII, No. 270) 1909, p. 133; De Toni Syll. Alg. IV, p. 1635,—*Fucus edulis* Turner Fuci II, t. 114; Gmelin, Hist. Fuc. Tab.

26 (partim).—*Iridaea edulis* Harv. Phyc. Brit. pl. 97; Kg. Tab. Phyc. XVII, t. 3, f. a-c.—*Sarcophyllis lobata* Kg. Tab. Phyc. XVII, t. 97, f. a-c.—*Schizymenia edulis* J. Ag. Sp. Alg. II, p. 172.—*Sarcophyllis edulis* J. Ag. Epicr. p. 265; Kjellm. Alg. Arct. Sea p. 125.

Fronde tufted rising from a small scutate disc, broadly membranous, gradually tapering below into cuneate base in elongated forms and abruptly in roundish ones, rarely simple and not lobed, assuming oblong, obovate or almost roundish shape, often curved to one side, usually clefted radially into some irregularly cuneate lobes, in some almost palmately lobed. Apices are rarely entire, usually more or less worn away by waves. Frond attains the height of 15-60 cm. and breadth of 5-30 cm., and the lobes 3-10 cm. in the breadth of upper broader portion. Margin entire or irregularly crenated. *Colour* purplish-red, turning to dark red in some fully grown frond. *Substance* membranaceous, and the plant firmly adheres to paper in drying.

Hab.: Common along the coasts of Kurile Islands and Hokkaido.

Pl. CLXXX. Fig. 1: frond of *Dilsea edulis* Stackh., $\frac{1}{1}$.—Fig. 2: another form of frond, shown in the outline, $\frac{1}{1}$.—Fig. 3: portion of the cross-section of frond, showing two auxiliary-cell-branches; line *aa* indicates the median portion of the section, $\frac{353}{1}$.—Fig. 4: auxiliary cell branch, $\frac{567}{1}$.—Fig. 5: portion of the cross-section of frond showing procarp; line *aa* indicates the middle portion of the section, $\frac{353}{1}$.—Fig. 6: tetraspores in the cross-section of frond, $\frac{220}{1}$.—Fig. 7: cortical structure, $\frac{353}{1}$.

Pikea californica Harv.

Nom. Jap. : *Michigaeso*.

PL. CLXXXI, Fig. 1-6.

Pikea californica Harv. Ner. Bor. Amer. II. p. 246; III. p. 131, tab. 49B; J. Ag. Epicr. p. 253; Id. Florid. Morph. t. 17, f. 6-10; DeToni Syll. IV, p. 1631; Coll., Hold. and Setch. Phycoth. Bor. Amer. XVIII, no. 897.—*Pikea?* sp. Okam. Nippon Sorui Meii (2nd., ed.) p. 114.

Fronds densely tufted rising from common scutate disc, ancipito-compressed, (1-1.5 mm. in diam.), thickened below to cylindrical stipe, without percurrent stem, but divided into many main segments which are subdichotomo-pinnately branched, 5-10 cm. high. Branches of every order widely parted, distichously disposed in an irregular manner, some alternate or opposite, others subfasciculate or subsecund, with longer and shorter ones intermixed without any definite order, and furnished with minute simple or branched ramuli. Central axis consists of cells of larger calibre, from which branches arise on all sides; of them those standing on the flank give rise to the central axis of lateral branches, while those on the surface-side remain short without developing to branches. From the cells of axis cortical cell-filaments arise, and rhizoidal cells which fill up the inner cavity of frond are abundantly produced both from axial and infra-cortical cells. In growing apex terminal cells are horizontally articulated.—*Fruits* of both kinds unknown. *Colour* beautiful purplish-red. *Substance* soft-cartilaginous and the plant imperfectly adheres to paper in drying.

Gymnogongrus flabelliformis Harv.

Nom. Jap. *Okitsunori*.

PL. CLXXXI, Fig. 7-9; PL. CLXXXII, Fig. 9-14.

Gymn. flab. Harv. in Gray's List of Jap. Pl. p. 332; Sur. Alg. Jap. p. 36, t. XXIV B., DeToni Phyc. Jap. nov. p. 25; Id. Syll. Alg. IV, p. 248; Okam. Nippon Sorui Meii (2nd. ed.) p. 32; Id. Alg. Jap. Exsic. Fasc. I, n. 10.—*Gymn. japonicus* Sur. Alg. Jap. p. 36, tab. 24a.

Fronds caespitose, rising from callous disc, narrow-linear, compressed, many times regularly dichotomo-flabellate, fastigiata, closely forking, with segments erecto-patent standing on roundish axils, and attain the height of 4-8 cm. Segments are usually linear and equally broad or a little cuneate toward forks, 1-1.5 mm. in breadth, but sometimes become very slender and almost filiform; margin with or without proliferations which are either simple or once or 2-3 times forked. Dichotomous segments are usually near to each other, but in some widely separated. Apex obtuse or pointed, sometimes slightly dilated and emarginated or bifid. *Cystocarps* produced in ultimate and penultimate segments, often 3-4 seriated in one row, slightly prominent on both surfaces. *Colour* vinoso-purple, becoming almost black in drying. *Substance* cartilaginous and the plant does not adhere to paper in drying.

Hab.: on rocks near high tide. Common along both coasts of

the country from Kyushu to the southern part of Hokkaido ; Chosen.

Phyllophora intricata Okam. n. sp.

Nom. Jap.: *Masago-tsunagi*.

PL. CLXXXII, Fig. 1-8.

Fronds forming intricate mass, erect, rising from creeping segments which are fixed to the substratum by small radical discs, flat, irregularly dichotomous, with or without short stipe, 5-7 cm. high. Fronds rather variable in shape, more or less dichotomous, but sometimes subpinnately branched. Segments patent with round axils. Branches adhere to each other at the places where they come in contact by forming root-like discs or simply by fusing together; they often become fixed to substratum by radical discs made on their apices and they emit, both from margins and surfaces, filiform or more or less broad and shortly stipitate segments, which more and more increase the intrication by the process just spoken about. Segments vary in breadth from 2 to 5 mm., some broadly linear, others almost leafy, while in extreme ones almost filiform (fig. 6). Apex of segments oblong, spatulate, ligulate or pointed. *Fruits* of both kinds unknown. *Colour* purplish-red. *Substance* soft cartilaginous and the plant does not adhere to paper in drying.

Hab.: washed ashore; Enoshima, Iwaki, Nō (Prov. Yechigo).

Late Mr. Yendo enumerates *Phyllophora palmettoides* J. Ag. in his Notes on Algae IV (Bot. Mag. Tokyo 1916, p. 59) which seems most probably to be the present plant. The present plant chiefly differs from that by having intricated and creeping segments and not having frond furnished with stem standing from callous disc.

Pl. CLXXXII, Fig. 1-8. Fig. 1-3: different forms of fronds of *Phyll. intricata* Okam. n. sp. from Enoshima, $\frac{1}{1}$.—Fig. 4-5: same from Prov. Iwaki, $\frac{1}{1}$.—Fig. 6: form with slender branches from Enoshima; from *b* to right more branches, not given in figure, $\frac{1}{1}$.—Fig. 7: branches fused together, $\frac{34}{1}$.—Fig. 8: cross section of frond, $\frac{353}{1}$. *r*, radical discs; *a*, adhering points.

Euptilota articulata (J. Ag.) Schm.

Nom. Jap.: *Iso-shinobu*.

Pl. CLXXXIII, Fig. 1-9.

Euptilota articulata (J. Ag.) Schmitz Klein. Beitr. Florid. VI (1896) p. 7; DeToni Syll. IV, p. 1370.—*Ptilota articulata* J. Ag. Sp. II, p. 100; Id. Epicr. p. 78; Kütz. Tab. Phyc. XII, t. 56, f. d-e.

Fronds filiform, ancipito-compressed, subcylindrical below, thickly branched in alternato-pinnate manner, with widely parted divisions, 5-10 cm. high. Basal portion or lower half of main branches are sometimes naked in well-grown frond, but the remaining portions are regularly provided with longer or shorter pinnae which arise alternately close to each other. Branches (fig. 2) are articulated in flexuose manner with subcubical or pentagonal cells in their upper portion of the axis, while the lower portion is more or less covered with rhizoidal cells which make their appearance from basal cells of pinnae. Cortication

K. Okam, del.

Euptilota articulata (J. Ag.) Schm. いそしのぶ, Fig. 1-9.

Asparagopsis hamifera (Hariot) Okam. かぎのり, Fig. 10-11.

Chrysymenia Uvaria (L) J. Ag. はなのえだ, Fig 1-9.
Asparagopsis hamifera (Hariot) Okam. かぎのり, Fig 10-16.

becomes thicker and thicker below, and in the thicker portion of branches the central axis is thickly covered with longitudinally running rhizoidal cells, and the cortical layer of a thicker branch consists of filiform cells. Pinnulae throughly ecorticated, arise alternately from every articulation of pinnae, and pinnellae are in similar arrangement. As the age of plant proceeds, pinnae grow up to branches, and pinnulae to pinnae. Length of articulation is subequal to or a little longer than the diameter through the whole length of frond. *Tetraspores* produced on pinnellae, sessile, tripartite. *Cystocarps* unknown. *Colour* pinkish-red. *Substance* membranaceous and the plant imperfectly adheres to paper in drying.

Hab.: Prov. Awa, Kii, and Shima.

Asparagopsis hamifera (Hariot) Okam.

Nom. Jap.: *Kagi-nori*.

PL. CLXXXIII, Fig. 10-11; PL. CLXXXIV, Fig. 10-16.

Bonnemaisonia hamifera Hariot Alg. de Yokoska p. 223; Okam. Nippon Sorui-Meii (2nd. ed.) p. 62; De Toni Syll. IV, p. 768.—

Hypnea adunca J. Ag. Collins, Hold. and Setch. P. B. A. n. 490.

Fronde forming entangled mass on other algae, with filiform, thicker, or cylindrical stem or main branches, 3-4 times pinnately branched, 10-15 cm. high. Branches alternate, patent, rising on all sides in pyramidal outline. They are densely covered with short, soft, hair-like ramuli. In spring, ramuli are very abundant and branches are penicillate, but, later they become less numerous and rather coarse, and assume somewhat comb-like appearance. Some of branches remain quite naked and swell up beneath the apex forming hooks by which branches entangle to each other. Ramuli are arranged in irregularly alternate (not strictly decussate) pairs; and main and lesser branches are also primarily arranged in the similar manner, but one of the pair being alternately suppressed, they become to assume alternate appearance. In sterile frond, ramuli are alternate, but in fertile ones reproductive organs are formed on one of the pair.—*Tetraspores* unknown. *Antheridia* oblong, shortly pedicelled. *Cystocarps* ovato-globose or globular, shortly stipitate. *Colour* purplish-red often fading to yellowish. *Substance* soft and the plant closely adheres to paper in drying.

Hab.: entangled on various algae between tide marks and below low tide; rather common from Prov. Awa to Hakodate.

Present plant which was put under *Bonnemaisonia* by Hariot is indeed *Asparagopsis*, as one can see from its filiform and penicillate branches and structure of frond.

Pterosiphonia bipinnata (P. et R.) Fkbg.

Nom. Jap.: *Ito-yanagi*.

PL. CLXXXV, Fig. 1-7.

Pterosiphonia bipinnata Fkbg. Rhod. p. 273; Setch. and Gardn. Alg. of northwest. Amer. p. 328; De Toni Syll. IV, p. 997.—*Po'yisiphonia bipinnata* Post. et Rupr Illustr. p. 22.—*Polyostea gemmifera* Rupr. Tange Ochot. Meer. p. 226, t. 11.

Fronds filiform, caespitose, soft, setaceous, 5-15 cm. high, erect, thoroughly ecorticated from the base, distinctly branched below in subdichotomopinnate manner and pinnately branched upward. Branches 2-3 times pinnate; in contracted upper portions of branches the arrangement of pinnae is more corymbose (fig. 3), while in elongated ones pinnae alternate on slightly flexuose rachis (fig. 2). Pinnules bend inward at the beginning, afterward becoming turned outward and patent; the apex of pinnae is almost level-topped with young pinnellae alternately arising from the inside of preceding ones. Pinnae and pinnulae stand on every third articulation, and end in an acute apex from broader base. Articulations in primary filament are shorter below, in the middle portion 3-5 times long as diameter, gradually diminishing in length upward, in upper branches becoming a little longer or shorter than the diameter. Axis is more or less torted with 13-14 pericentral cells. *Tetraspores* seriated in a longitudinal row in upper pinnae which are

Pterisophoma binnata (P. et F.) Edlenb. いどやなぎ Fig. 1-7.
Pterisophoma artica (J Ag.) Setch. and Gardner いなぼぐさ Fig. 8-16.

not changed in form. *Cystocarps* unknown. *Colour* dark brownish and almost black in dried state. *Substance* membranaceous and the plant imperfectly adheres to paper in drying.

Hab.: Chishima (Kurile Isls.)

Pl. CLXXXV, Fig. 1-7. Fig. 1: frond of *Pterosiphonia bipinnata* (P. et R.) Fkbg., $\frac{1}{1}$.—Fig. 2: terminal portion of branch, showing alternate arrangement of pinnae, $\frac{83}{1}$.—Fig. 3: contracted terminal branches, $\frac{16}{1}$.—Fig. 4: growing point of branch; *a*, apical cell; *b*, *b'*, *b''*, apices of lateral branches, $\frac{353}{1}$.—Fig. 5: cross-section of branch; compressed one is that of upper branch; cylindrical one, lower, $\frac{50}{1}$.—Fig. 6: longitudinal section of branch, $\frac{10}{1}$.—Fig. 7: branch bearing tetraspores, $\frac{48}{1}$.

***Pterosiphonia arctica* (J. Ag.) Setch. and Gardn.**

PL. CLXXXV, Fig. 8-16.

Nom. Jap.: *Inabo-gusa*.

Pterosiphonia arctica (J. Ag.) Setch. and Gardn. Alg. north-west. Amer. p. 329.—*Polysiphonia arctica* J. Ag. Sp. II, p. 1034; Kjellm. Alg. Arct. Sea p. 123.

Only two ill-prepared specimens now before us. *Fronde* filiform, soft setaceous, complanated above, erect (?), dichotomo-pinnately branched below, subfastigiately approximated above in subcorymbose manner. Ramuli arise alternately at acute angles on slightly flexuose elongated rachis, short, distichous, ending in an acute apices from broader bases. Branches and ramuli are slightly united at base and stand intercepting mostly two articulations. On the dorsal side of branches and branchlets near their apical cells very short, almost rudimentary hairs are provided

(fig. 10 and 12). Often root-fibres are emitted from the apices of stunted or harmed ends of ramuli. Pericentral cells are 6 in ours and thoroughly ecorticated. Articulations 6 times long as diameter in main filaments (cells in that portion measure 2-3 mm. in length and 220-250 μ in thickness), gradually becoming shorter above, in upper ramuli becoming subequal to or shorter than the diameter. *Tetraspores* seriated in a longitudinal row in upper unaltered ramuli. *Cystocarps* unknown. *Colour* darkish-brown in dried state. *Substance* soft and the plant imperfectly adheres to paper in drying.

Hab.: Myedoni Isl. in Komandorski IIs.

Setchell and Gardner remark that *Pterosiphonia arctica* has no hair, but in ours it is provided though rather rudimentary. The presence of hairs in *Pterosiphonia*, contrary to Falkenberg's statement, has already been shown in *Pterosiphonia-fibrillosa* Okm. Icones Vol. II, p. 172-176, Pl XCVIII, 1912.

Rhodomela subfusca (Woodw.) C. Ag.

Nom. Jap.: *Ito-fujimatsu*.

PL. CLXXXVI; PL. CLXXXVII, Fig. 1-13.

Rhodomela subfusca (Woodw.) C. Ag. Sp. I, p. 378; J. Ag. Sp. Alg. II, p. 883; Harv. Phyc. Brit. tab. 264; Falkenb. Rhodom. p. 593, tab. XI, f. 2-17; Kjellm. Alg. Arct. Sea p. 113; Börgesen The Mar. Alg. of the Faeroes, 1902, p. 375; Hauck Meeresalg. p. 217, f. 94; Okam. Synop., 日本藻類名彙 (1st. edit.), p. 66.—*Fuscaria tenuissima* Rupr. Alg. Ochot. p. 221, tab. 10.—*Fucus subfuscus* Woodw., Turn. Fuci tab. 10.—*Rhodomela lycopodioides* (L.) Ag., Okam. Synop., 日本藻類名彙 (2nd. edit.), p. 81.

Many fronds rising from a common disc, 13-20 cm. high, 3-4 times pinnately branched in more or less regular manner from the lower portion of frond. Fronds are filiform, in some very slender, in others more thick and in perennial older ones the lower portion of frond often becomes firm and stem-like (Pl. CLXXXVI, fig. 1). Branches are patent, in some almost straight, in others slightly flexuose, the middle ones in general the longest and are more or less densely covered with ramuli. Ramuli simple or often furnished with few pinnate ramelli toward their apices; they are spirally arranged, subulate and incurved (fig. 2 and 4), in older ones often recurved (fig. 1). They are 10-12 mm. long in longer ones (fig. 2), 0.5-1 mm. in shorter ones (fig. 3).—*Tetraspores* are formed in ramuli which become toruloso-prominent in maturing (Pl. CLXXXVII, fig. 9-10); in some fronds a small branch bearing tetrasporic ramuli becomes stunted appearing like fasciculately arising from the axil of a ramulus (fig. 8). *Antheridia* oblong, formed on

“Haarblättern” arising from the apices of ramuli. *Cystocarps* ovate provided with a wide ostiole, shortly stipitate on the side of ramuli. *Colour* dark or yellowish brown when fresh, turning to blackish in drying. *Substance* soft in younger part, becoming firmer in older portions and the plant imperfectly adheres to paper in drying.

Hab.: On rocks between tide-marks, rather near the high tide in the place where it is protected from the dashing of waves. Widely distributed within the boundaries from the Kurile to Kyushyu.

The specific determination of the species of *Rhodomela* is very difficult in *Rh. subfusca*, *virgata* and *lycopodioides*, and there are some confusions among them. To a certain extent I have followed Kjellman's definition of the species, and many forms are met with in our specimens differing in several minute characters chiefly according to their localities and they may be separated in other days into some numbers of varieties.

Plants illustrated in PL. CLXXXVI may be considered in some measures as the representatives of forms of the plant in this country. Of the two species of *Rhodomela* known in the boundaries the present plant has a wide range of distribution ranging from Shimushu to Kyushyu and as consequence there are many types of different forms. Fig. 4 represents the southern form and fig. 1, the northern; fig. 3 may be considered as weakly grown form as it is collected at Abashiri where the coast is washed by a terminal branch of the warm current pouring into the Ochotsk Sea. The form shown in fig. 2 which I have collected at Muroran in the summer has a very robust frond having a very different appearance.

PL. CLXXXVI. Fig. 1: plant from Shimushu Isl., bearing vernal shoots just growing from the hiemal frond, $\frac{1}{2}$.—Fig. 2: plant collected at Muroran in summer, 1915, $\frac{1}{2}$.—Fig. 3: plant from Abashiri in summer, 1915, $\frac{1}{2}$.—Fig. 4: summer form from Iwaizaki, $\frac{1}{2}$.

Nemalion multifidum (W. et M.) J. Ag.

Nom. Jap.: *Tsukumo-nori*.

PL. CLXXXVII, fig. 14-16.

Nemalion multifidum (W. et M.) J. Ag. Sp. Alg. II, p. 419; Id. Epier. p. 508; Id. Florid. Morph. t. 29, f. 1; Harv. Phyc. Brit. t. 36; Kütz. Tab. Phyc. XVI, Tab. 61; Farlow Mar. Alg. New England p. 117, t. 12, f. 1; De Toni Syll. Alg. IV, p. 78.

Fronds filiform, weak, few from a small disc, worm-like, about 10 cm. high, 1 mm. thick, gradually tapering above, many times irregularly and somewhat divaricately dichotomous with round and broadly obtuse axils. Peripheral filaments moniliform with the lower articulations little longer than thick, gradually becoming larger and globular above, attaining ca. 120 μ in thickness in the uppermost joint. *Colour* dark brownish

red in dried specimens. *Substance* gelatinous and the plant firmly adheres to paper in drying.

Hab.: Prov. Awa in Shikoku. *Rare*.

Rhodomela Larix (Turn.) C. Ag.

Nom. Jap.: *Fujimatsumo*.

PL. CLXXXVIII, fig. 1-4.

Rhodomela Larix (Turn.) C. Ag.; Post. et Rupr. Illustr. p. 14, t. 38, f. h; Harv. Ner. Bor. Amer. II, p. 24; J. Ag. Sp. Alg. II, p. 886; Kjellm. Alg. Arct. Sea, p. 117; Falkenb. Rhodom. p. 600, t. XI, f. 1; Okam. Synop. (2nd ed.) p. 81; Okam. Alg. Jap. Exsic. no. 73; De Toni Syll. Alg. IV, p. 1131.—*Fuscaria Larix* Rupr. Alg. Ochot. p. 27.—*Lophura Larix* Klg. Sp. Alg. p. 850; Id. Tab. Phyc. XV, t. 39, f. a-c.—*Fucus Larix* Turn. Fuci IV, p. 24, tab. 207.

Fronds erect, coespitose rising from a callous disc with a cylindrical stem, 1-1.5 mm. thick, 15-25 cm. long, undivided, but beset from top to bottom with branches of the same nature and substance as itself, patent, disposed in an irregularly spiral alternate manner (some 10 cm., others scarcely 3-5 mm. long, the middle ones in general the longest), all like the stem beset with patent ramuli growing in small clusters with a very short interval between each cluster, simple, subulate, 2 or 3 mm. long, and scarcely thicker than hog's bristles. This clustered arrangement of the ramuli is more evident in the branches and toward the upper part

of the stem than near the base, where they grow rather solitary and are imbricated on all sides, but so loosely that the stem is everywhere seen through them.—*Stichidium* transformed from ramuli on shortened axis which grows from axil of a sterile ramulus, incurved and clustered, and half times as thin and as short as the sterile ramulus, cylindrical and filiform. *Colour* deep dark brown when recent, turning to almost black when dried. *Substance* cartilaginous, flexible and tough; in drying the plant scarcely changes its appearance and adheres though very slightly to paper.

Hab.: on rocks in open coast between tide-marks near high tide. From Kurile Isls. to Rikuzen.

Present plant grows on open coast where waves dash against. In a place where *Rhodomela subfusea* and *R. Larix* grow near to each other, the former prefers the sheltered sides, while the latter stands fronting the dash of waves.

PL. CLXXXVIII, fig. 1-4. Fig. 1: frond of *Rhodomela Larix* (Turn.) C. Ag., $\frac{1}{1}$.—Fig. 2: tetrasporic frond from Shimushu (6, May), $\frac{1}{1}$.—Fig. 3: terminal portion of branch bearing tetraspores, $\frac{16}{1}$.—Fig. 4: one of branchlets bearing stichidia shown in fig. 3, $\frac{48}{1}$.

Polysiph. calacantha Harv. Char. New Alg. p. 330.

Fronds entangled among other algae, erect, fine, filiform, laterally branched. "Langtriebe" surrounded throughout the whole length with spirally arranged, $\frac{1}{4}$ -alternately branched "Kurztriebe" or lateral branches which have the appearance of short stipitated star-shaped glomerules. Branches widely parted or almost horizontal. Star-shaped glomerules consist of short, thick, conical, divaricately branched polysiphonous horns which are further branching. Sometimes elongated, single-celled, hair-like root-fibres are emitted from the middle of the cluster of star-shaped horns, which attach the plant to other bodies occasionally forming disc-shaped expanded holdfast at the apex. Articulations subequal to the diameter or a little shorter. Filaments cylindrical or more or less quadratic in cross-section. *Colour* dark brownish red. *Substance* soft membranous and the plant does not firmly adhere to paper in drying.

Hab.: entangled on algae. Ryukyu, Ogasawarajima, Boshyu.

Antithamnion Plumula (Ellis) Thur. よつがさね

Antithamnion Plumula (Ellis) Thur.

Nom. Jap.: *Yotsu-gasane*.

PL. CLXXXIX.

Antithamnion Plumula (Ellis) Thur. in Le Jolis List Alg. Cherb. (1863) p. 112; Hauck Meeresalg. p. 71; Okam. Synopsis (2nd. edit.) p. 95.—De Toni Syll. Alg. IV, p. 1400.—*Conferva Plumula* Ellis; Dillw. Brit. Conf., 1809, t. L.—*Callithamnion Plumula, refractum*, and *polyacanthum* Kütz. Tab. Phyc. XI, t. 83-84.

Fronds fine, filiform (some ca. 150 μ thick in the middle portion), deliquescently branched in dichotomo-pinnate manner, furnished beneath the apex of every articulation with opposite or 4-verticillate, tetra-stichously arranged "Kurztriebe." "Kurztrieb" on its inner that is upper side carries laciniae arranged in a secund manner, and are almost horizontal or refracted in older and lower ones, patent or widely parted above; laciniae simple or furnished with a few similarly arranged divaricated lacinulae. "Kurztriebe" distichously arising on the flank of rachis are decomposed, while those alternating with them on the same articulation are more simple or sparingly branched. Apices of all sorts of branches are acute and sharp. Root fibres are transformed from "Kurztriebe" arising from lower articulations of frond. Articulations 2-6 times long as diam., becoming shorter and subequal toward the apex as well as the base of frond, cylindrical or slightly narrowed in the middle. On the sides of upper articulations of young laciniae or "Kurztriebe" gland-cells containing hyaline or yellowish mass are usually seen.—*Tetraspores* globular or oval, mostly cruciate, situated solitary or a few aggregated on the side of laciniae or lacinulae, mostly sessile, rarely shortly pedicellated. *Cystocarps* large, globular, with 2-3 nuclei aggregated

on the apex of upper branches and surrounded by "Kurztriebe." Colour rosy-red. Substance membranaceous and the plant imperfectly adheres to paper in drying.

Hab.: entangled on other algae. Hakodate, Enoshima.

7 2 13 10 8 15 3 1 5 11 6 4 12 9 14

Chondrococcus Hornemanni (Mert.) Schitz ほそばなみのはな Fig. 1-14

Chondrococcus Japonicus (Harv.) Okam. なみのはな Fig. 15

1-2 mm. broad. Main branches irregularly alternate, rather naked below, with lower branches the usually longest, becoming gradually shorter above; branches of every order are in similar mode of ramification, furnished along the margins with sharpish or often deltoideo-obtuse simple or divaricated teeth. All the branches very patent arising on rather roundish axils, straight or rolled up at apices. Glandular cells full of yellowish contents are scattered beneath the cortex. In some cases fronds bearing slenderer branches are seen which have an appearance quite differing from the normal ones (fig. 2-3).—*Tetraspores* forming irregularly roundish nemathecium, slightly elevated, and arranged often in row along the margins or on the intramarginal surfaces of branches. *Cystocarpic* warts are similar in the shape and position as tetrasporic nemathecium. *Colour* deep red. *Substance* rigid when fresh, soon turning to subgelatinoso-membranaceous and the plant pretty well adheres to paper in drying.

Hab.: on rocks between tide-marks near low tide; from Ryukyu to Rikuzen; Tango and Echigo.

Chondrococcus japonicus (Harv.) Okam.

Nom. Jap.: *Namino-hana*.

PL. CXC, Fig. 15.

Chondrococcus japonicus (Harv.) Okam. Alg. Jap. Exsic. no. 35 (1899).—Matsumura and Miyoshi Cryptog. Jap. Icon. Illustr., 1901, vol. I. no. 12, pl. 58.—*Chondroc.?* *japonicus* (Harv.) De Toni Phyc. Jap. Nov. (1895) p. 39; Id. Syll. Alg. IV, p. 1677.—*Desmia japonica* Harv. Char. new Alg. (1859) no 23; Okam. in Bot. Mag. Tokyo, 1893, p. 321 (tetraspore).

Mode of ramification, characters of the both kinds of fruits are all similar to those of *Ch. Hornemanni*, only differing in the breadth of frond and form of ultimate pinnellae or marginal laciniae. Fronds are compresso-flat, broadly linear, 2-3 mm. broad, with often blunt and obtuse, crenulated and irregularly placed pinnellae or marginal processes. Often there are many forms having the appearance intermediate between the two species which are to be separated scarcely one from the other, fronds being more narrow and branches being sharply pointed.

第 CLXXXVI 圖版ニ示シタル體形ハ幾分邦内ニ産スル本種ノ代表ト見做スヲ得可シ. 邦内ニ産スル本屬ノ二種中本種ハ弘キ分布ヲ有シ占守島ヨリ九州ニ亘ル, 隨テ種々ノ體型アリ. 第四圖ハ南方ノ形ニシテ第一圖ハ北方ノモノナリ, 而シテ第三圖ハ纖弱ナル體形ノモノト考フルヲ得ベシ, 蓋シ該種ハ北海道網走ニテ採集シタルモノニシテ其處ニハ暖流ノ末派ガオコツク海ニ注ク所ナレバナリ. 第二圖ニ示シタルモノハ

大正四年ノ夏季室蘭ニ於テ採集シタルモノニシテ極テ強盛ナル體形ヲ有シ、他ノ體形ト甚シク異ナル外觀ヲ呈ス。

第 CLXXXVI 圖版. 1: 越冬セル體ヨリ方サニ春季ノ新條ヲ伸長シタルモノ, 占守産, $\frac{1}{1}$.—2: 夏季ノ室蘭品, $\frac{1}{1}$.—3: 夏季ノ網走品, $\frac{1}{1}$.—4: 夏季ノ陸前磐井岬品, $\frac{1}{1}$.

第 CLXXXVII 圖版. 1-13 圖. 1: 實ナキ枝ノ頂部ニシテ小枝及最末枝ノ配列ヲ示ス, $\frac{13}{1}$.—2: 體ノ成長點, $\frac{353}{1}$.—3: 一ノ軸ノ頂端ニ近ク存スル小枝ノ頂端ニシテ毛狀枝, h , ト頂細胞, a , トヲ示ス, $\frac{353}{1}$.—4: 體ノ横斷面; c , 中軸細胞, $\frac{220}{1}$.—5: 體ノ縱斷面; c , 中軸細胞, $\frac{220}{1}$.—6: 枝ノ頂部ニシテ精子器ヲ有スルモノ, $\frac{16}{1}$.—7: 精子器, $\frac{83}{1}$.—8: 短縮セル枝ニ四分胞子ヲ有スル小枝ヲ附ケタルモノ, 稍廓大.—9: 通常ノ枝(短縮セザル)ニ在ル四分胞子ヲ熟セル小枝, $\frac{22}{1}$.—10: 「ステイキジア」ノ側面ヨリ四分胞子ヲ見タルモノ, $\frac{48}{1}$.—11: 四分胞子ト蓋細胞トヲ示ス, $\frac{220}{1}$.—12: 囊果ヲ有スル枝, $\frac{13}{1}$.—13: 囊果, 稍廓大. (1, 3, 4-5, 11-12 圖ハ小名濱産ノ「アルコホール」品ヨリ畫ク).

Nemalion multifidum (W. et. M.) J. Ag.

つくものり.

第 CLXXXVII 圖版. 14-16 圖.

體ハ絲狀, 軟弱, 數莖同一ノ小盤狀根ヨリ出デ, 蠕虫狀ヲナシ, 高サ約 10 cm. 太サ約 1 mm., 漸次上方ニ細ク, 數回不規則ニ叉狀ニ分レ腋圓クシテ廣開ス. 類化絲ハ念珠狀ヲナシ其下部ノ關節細胞ハ太サヨリモ稍長ク漸次上方ニ大キク且球狀ヲナシ, 最上部ノ細胞ハ太サ約 120 μ アリ. 色ハ乾燥品ニテ暗褐紅色ナリ. 質ハ粘柔ニシテ體ハ密ニ紙ニ附着ス.

產地：阿波那賀郡答島（明治十六年水産博覽會出品）；稀ナリ。

第 CLXXXVII 圖版, 14-16 圖. 14: つくものり, *Nemalion multifidum* (W. et M.) J. Ag. ノ體, 1.—15: 腊葉品ノ體ノ横断面, 直徑 0.8 mm.; $\frac{1.5}{1}$.—16: 類化糸ト根様細胞, $\frac{3.5}{1}$.

Rhodomela Larix (Turn.) C. Ag.

ふぢまつも 岡村稱.

第 CLXXXVIII 圖版, 1-4 圖.

根ハ小塊狀根. 體ハ直立シ, 圓柱狀ノ莖ヲ以テ叢生ス, 高さ 15-25 cm, 1-1.5 cm. 太ク, 一條ノ主幹ヲ存ス, 而シテ頂端ヨリ基部ニ至ル迄幹ト同様ノ枝ヲ存シ, 枝ハ廣開シ, 不規則ナル螺旋狀ヲナシテ互生ニ配置シ (或モノハ 10 cm, 他ノモノハ 3-5 mm. 長ク, 中央ノモノ一般ニ最モ長シ) 幹ト同様ニ總テ廣開セル小枝ヲ以テ蔽ハル; 小枝ハ小サキ叢ヲナシ, 各叢ノ間ニ極メテ短キ間隔ヲ存シ, 單條ニシテ錐狀ヲナシ, 2-3 mm. 長ク, 獸毛 (豚) 程ノ太サアリ. 小枝ノ此叢生セル排列ハ枝ニ於テ殊ニ明ニシテ且莖ノ下部ヨリモ上部ノ方ニ能ク視ルコトヲ得ベク, 下部ノ方ニテハ各方面ニ覆瓦様ニ並列スレドモ寧ロ疎トナリ爲ニ莖ハ全部露出スルニ至ル. —「スチキジア」ハ小枝ノ腋ヨリ生ズル短縮セル軸ニ在ル小枝ヨリ變成シ, 内方ニ屈曲シテ叢生シ, 中性ノ小枝ノ半分程ノ細サニシテ其ヨリモ短ク, 圓柱狀絲狀ナリ. 色ハ生鮮ノ時ハ濃キ暗褐色ニシテ乾燥スルトキハ殆ト黑色トナル. 質ハ軟骨質ニシテ屈撓性ヲ有シ強靱ナリ; 乾燥スルニ至ルモ體ハ餘リ外貌ヲ變セズ, 紙ニ附着スルコト不完全ナリ.

產地：開濶ナル沿岸ノ岩石ニ生ジ高潮線ニ近ク潮線間ニ生ズ. 千島ヨリ陸前ニ至ル.

分布：北部太平洋。

本植物ハ開濶ナル沿岸ニ於テ波浪ノ衝ニ當ル所ニ産ス。本種ト Rh. subfusca ト互ニ近ク生ズル所ニテハ後者ハ波ノ蔭トナル所ニ在レドモ、前者ハ其衝ニ當ル所ニ産ス。

第 CLXXXVIII 圖版, 1-4 圖. 1: ふぢまつも, Rhodomela Larix (Turn.) C. Ag. ノ體, $\frac{1}{1}$ —2: 五月六日占守島産ノ四分胞子ヲ有スルモノ, $\frac{1}{1}$ —四分胞子ヲ有スル枝ノ頂部, $\frac{16}{1}$ —4: 第3圖ニ示シタル「スチキジア」ヲ有スル小枝ノ一ツ, $\frac{48}{1}$.

Roschera Sonder 1879.

いとくづぐさ屬.

RHODOMELACEAE ふぢまつも科.

體ハ直立シ、他ノ海藻ノ間ニ纏絡シテ立チ、絲狀ニシテ各方面ニ分岐ス、多管軸ハ4周心管ヲ有シ全部皮層細胞ヲ被ムラズ。長條枝ハ其全長ニ於テ $\frac{1}{4}$ ノ列序ヲ以テ螺旋狀ニ交互ニ出タル短キ分岐セル側枝ヲ以テ蔽ハレ、側枝ハ有限成長ノモノニシテ宛モ柄ヲ有シタル星狀ノ小塊ノ如キ形狀ヲナス。長條ノ伸長ハ水平ノ分裂面ヲ有スル頂細胞ヲ有シ其各關節細胞ハ一條ノ毛狀葉トナルベキ初期ノ細胞ヲ分裂ス；此初期ノ細胞ハ直ニ枝トナリテ伸ビ、數個ノ枝ナキ關節細胞ヲ分裂シタル後其上部ハ更ニ同様ニ分岐ス。枝ノ短縮シテ分岐シタル部分ニ於テ下部ニアル 3-5 ノ毛狀葉トナルベキ初期ノ細胞ハ圓錐狀ノ、太キ、廣開セル、多管軸ノ刺トナリ(其刺ハ更ニ分岐セントスル形跡ヲ有スルコトアリ)而シテ上部ノモノハ常ニ微弱ナル發育ヲナシテ、單管ニシテ分岐セザル毛狀葉トナリテ各刺ノ中央ヨリ發出ス。毛狀葉ト刺トノ間ヨリ往々毛ノ如キ根ヲ生ジ、此根ハ折々其先端扁平ナル盤狀ニ展ガリ體ヲ他物ニ固着セシム。側枝トナルベキ初期ノ細胞ハ星狀ニ短縮シタル枝トナル代リニ多少長ク伸タル長條枝トナルコトアリ、——生殖器

ハ星狀ノ小塊ヲナセル部分ニ形成セラレ、其部ハ之ガ爲ニ特ニ變形スルコトナシ。四分胞子ハ太キ刺ニ生ジ或ハ星狀ノ小塊ヲ有スル軸ニ形成セラル、微弱ナル星狀ノ小塊ニ生ジ、時ニ一個、時ニ2-3個形成セラル、而シテ外方ニ突起セル瘤ノ如キ形狀ヲナシ、其之ヲ生ズル關節ニ一個ヅ、生ジ、交互ニ配置セラレ、外部ニハ2-3個ノ同長ナル蓋細胞ヲ以テ蔽ハル。精子器ハ未詳。胎原列ハ星狀塊ノ真中ニ少數形成セラレ、單管ナル毛狀葉ノ關節ニ存ス；囊果ハ卵形ニシテ、小サク、星狀塊ノ真中ニ通常一個形成セラレ、殆ド無柄ニシテ、星狀ノ枝ヲ以テ圍マル。果皮ハ可ナリ薄シ；胞子ハ割合ニ大ク、棍棒狀ナリ。

印度洋及太平洋ノ暖部ニ1種若クハ2種ヲ産シ往々可ナリ變形ス。下記ノモノハ模範種ナリ。一屬ノ名ハ Roscher 氏ノ名ニヨル。

Roschera glomerulata (C. Ag.) Web. v. Bosse.

いとくづぐさ 岡村稱。

第 CLXXXVIII 圖版, 5-10 圖。

體ハ他ノ海藻ノ間ニ錯綜シテ立チ、絲狀ニシテ側面ニ分岐ス。長條枝ハ其全長ニ於テ螺旋狀ニ配列セル、 $\frac{1}{2}$ ノ序列ヲ以テ互生セル短條枝即チ側枝ヲ以テ圍繞セラレ、其側枝ハ短キ柄ヲ有スル星狀ノ小塊ノ如キ觀ヲ呈ス。枝ハ廣開シ或ハ殆ド水平ニ出ヅ。刺狀ノ小塊ハ短キ太キ圓錐狀ノ廣開セル多管軸ノ刺ヨリ成リ、刺ハ更ニ分岐スルコトアリ。時トシテハ長キ單細胞ヨリ成レル毛狀ノ根アリテ、星狀ノ小團塊ノ中央ヨリ出デ、往々其頂端ニ盤狀ニ展ガリタル附着器ヲ形成シテ體ヲ他物ニ固着セシム。關節ノ長サハ其徑ト略ホ同長若クハ稍短シ。體ハ圓柱狀又ハ多少角張リタリ。色ハ暗紅褐色ナリ。質ハ軟キ膜質ニシテ乾燥スル時ハ紙ニ固着セズ。

產地：他ノ海藻ニ纏絡ス。琉球，小笠原島，房州。

分布：熱帯部 オーストラリア，太平洋諸島，印度洋，亞弗利加，日本。

Ahnfeltia concinna J. Ag.
Delesseria Middendorffii Rupr.

さいみ Fig. 1-7.
 ふがこのはり Fig. 8-11.

Ahnfeltia concinna J. Ag.

PL. CXCI, Fig. 1-7.

Nom. Jap.: *Saimi*.

Ahnfeltia concinna J. Ag. Sp. Alg. II, p. 312; Id. Epicr. p. 207; De Toni Syll. Alg. IV, p. 256; Yendo Notes on Alg. new to Jap. V, p. 256.—*Gymnogongrus implicatus* Kütz. Sp. Alg. p. 789; Id. Tab. Phyc. XIX, t. 69; J. Ag. Sp. Alg. II, p. 312.

Fronde gregarious, covering a wide range of area, erect, horny, subcylindrical, 5-15 cm high, 1-2 mm in diam., substipitate for a more or less long distance from the base, sometimes quite simple, but more usually divaricately branched upward in a ditrichotomous manner, and provided with proliferous branches, which often arise fasciculately or are arranged in secund manner. Segments cylindrical or slightly compressed, often corrugato-flexuose, and widely parted with an acute axil. *Cystocarps* many approximated in upper segments, slightly swollen out forming warty prominences. *Colour* dark purple or greenish, changing to blackish in drying. *Substance* horny and the plant does not adhere to paper in drying.

Hab.: On rocks extending from the mid-tide to little over the high tide mark, covering a wide range of area measuring 8-10 feet in height. Ogasawarajima, 7 islands of Idzu, Bosyu, Sagami, Ise.

PL. CXCI, fig. 1-7. Fig. 1: fronds of *Ahnfeltia concinna*, J. Tetrasporic Sporophylls of *Delesseria Middendorffii* Rupr.

PL. CXCI, Fig. 8-11.

Addition to the description of *Delesseria Middendorffii* illustrated in the Icones Vol. II, no. 7, p. 118-120, PL. LXXXIV—LXXXV, fig. 1-7.

Tetrasporic sporophylls are proliferated solitarily or subfasciculate^{ly} from the both sides of the midrib on both surfaces, globular, oval, oblong or obovate, thick and slightly depressed, shortly petiolated, sometimes winged along the margin, 1.5-2.5 mm long, 1.5-2 mm broad. In the cross-section of sporophyll two layers of tetraspores are observed on the upper and lower sides of the primary or fundamental layer and on both sides of the midrib. They are formed from sub-cortical cells lying between the epidermal and primary layers.

PL. CXCI, fig. 8-11. Fig. 8: leaf bearing tetrasporic sporophylls of *Delesseria Middendorffii*, Rupr., $\frac{1}{1}$.—Fig. 9: portion of the same, $\frac{5}{1}$.—Fig. 10: sporophyll seen from the marginal side, magd.—Fig. 11: half of the cross section of sporophyll, $\frac{48}{1}$.

Laurencia pinnatifida (Gm.) Lam.

Nom. Jap: *hane-sozo*.

PL. CXCII.

Laurencia pinnatifida (Gm.) Lamour. Essai p. 42; J. Ag. Sp. Alg. II, p. 764; Id. Epicr. p. 656; Kütz. Sp. Alg. p. 856; Id. Tab. Phyc. XV, Tab. 66, f. a-c; Harv. Phyc. Brit., Tab. 55; Hauck Meeresalgen, p. 208; De Toni Syll. Alg. IV, p. 798; Okam. Synop. 日本藻類名彙 (2nd. ed.) p. 69.—*Fucus pinnatifidus* Gmel. Hist. Fuc. p. 156, t. 16, f. 3; Turn. Hist. Fuci, t. 20.

Fronde coespitose, rising from a scutate disc, 5-15 cm high, almost cylindrical at the base, more or less compressed upward,

Laurencia pinnatifida (Gm.) Lam. はねそぞ

K. Okam del

Laurencia obtusa (Huds.) Lamour. みつでそび.

F.O'am. del.

5 8 2 J

1-4 mm broad for the most part, 0.5-1 mm broad in the ultimate pinnellae, 2-3 times pinnately branched in disticho-alternate manner. Branches almost linear, often narrowed toward the base, or little broader upward, patent, standing on the angle of almost 45° , roundish or lobed at apices. Outline of branches is pyramidal, lower branches being the longest. Pinnellae simple, linear or linear-clavate, truncated or expanded toward apex, often much lobed. Tetraspores aggregated at the apical portion of pinnellae which do not change their form. *Cystocarps* ovato-urceolate with wide ostiole, sitting at the side of pinnulae. *Colour* dark purplish, often fading to greenish-yellow. *Substance* fleshy, soon becoming soft; the plant pretty well adheres to paper in drying.

Hab.: On rocks below low-tide. Common along the Pacific side from Ryukyu to Hakodate, and the Japan Sea.

PL. CXCII. Fig. 1-3: different forms of the frond of *Laurencia pinnatifida* (Gm.) Lamour., $\frac{1}{1}$.—Fig. 4: cross-section of branch, $\frac{8}{1}$.—Fig. 5: portion of branch magd., $\frac{7}{1}$.—Fig. 6: branch bearing tetraspores, $\frac{7}{1}$.—Fig. 7: tetraspores seen through the surface of frond, $\frac{220}{1}$.—Fig. 8: tetraspores, $\frac{220}{1}$.—Fig. 9: cystocarps, $\frac{10}{1}$.—Fig. 10: vertical section of a cystocarp, $\frac{48}{1}$.

Laurencia obtusa (Huds.) Lamour.

Nom. Jap.: *mitsude sozo*.

PL. CXCIII.

Laurencia obtusa (Huds.) Lamour. Essai, p. 42; J. Ag. Sp. Alg. II, p. 750; Id. Epicr. p. 653; Harv. Phyc. Brit. t. 148; Kütz. Sp. Alg. p. 854; Id. Tab. Phyc. XV, t. 54-55; De Toni Syll. Alg. IV, p. 791; Hauck Meeresalg. p. 206.—*Fucus obtusus* Turn. Hist. Fuci t. 21.—Okam. Synop., 日本藻類名彙 (2nd. ed.) p. 69.

*Fronde*s often forming somewhat intricate mass, cylindrical,

more than 0.5-1.5 mm thick, mostly branched pinnately in paniculate outline. Branches and branchlets alternate or opposite, here and there arising to 3 or more in almost verticillate manner, patent or almost horizontal. Ramuli cylindrical or clavate, truncated or almost round at apices, simple or longer ones again branched beneath their apices, 1-10 mm long and 300-900 μ thick, often triparted.—*Tetraspores* collected beneath a little thickened apex of ramuli. *Cystocarps* oval, sessile, sitting along the side of upper branches and branchlets. *Colour* dark purple, often fading to greenish or yellowish. *Substance* soft cartilaginous when recent, and the plant imperfectly adheres to paper in drying.

Hab.: On rocks between tide-marks often near high tide. Common along the warmer part of the country.

PL. CXCIII. Fig. 1-3: different forms of *Laurencia obtusa* (Huds.) Odonthalia ochotensis (Rupr.) J. Ag. Sp. Alg. II, p. 897; De Toni Syll. Alg. IV, p. 1140.—*Atomaria ochotensis* Rupr. Alg. Ochot. p. 20 (212), tab. 9.

Fronds coespitose, rising from a common scutate disc (?), flat, linear, alternately decompose-pinnate, distichous, thickened below into sub-cylindrical stem, soon complanated above; in the lower portion of frond margins are rough by remains of dropped branches. In older frond the lower portion is transformed into a thick cylindrical stem, and the plant attains the height of 20-30 cm. Rachis scarcely exceeding 1 mm. in breadth, evidently provided with midrib and marginated, gradually becoming a little broader and more membranaceous upward, 1.5-2 mm. in breadth. Midrib becomes prominent by evolution of cortical layers almost occupying the median portion of branch and very gently flexuose. Pinnæ arise from margin, and similarly shaped pinnæ also proliferated from margins are attenuated at the base in young stage, but when fully grown become almost equally broad. Sterile ones are elongated, while fertile ones more contracted, more flabellate and all stand erecto-patent. Pinnulae dentiform or elongated, in some almost subulate, slightly incurved in upper ones.—*Stichidia* formed in terminal or lateral pinnæ, flabellato-corymbose, pinnato-fasciculated, each provided or not provided with a short pedicel, linear-lanceolate, slightly contracted at every articulation, containing double row of tetraspores that is with two oppositely placed tetraspores in a single articulation. *Cystocarps* obliquely situated beneath the apex of pinnule and calcalated,

ovato-urceolate, somewhat contracted at orifice. *Colour* fuscous. *Substance* membranaceous and the plant does not adhere to paper in drying.

Pterosiphonia parasitica (non Fkbg.) Yendo Notes on Alg. New to Jap. VIII. (Bot. Mag. Tokyo Vol. 32, 1928, p. 78).

Fronde dwarf, filiform, creeping or erect, standing from basal creeping portion where the plant adheres to other algae by emitting root fibres from the under-surface, thoroughly ecorticated, alternato-pinnately decomposed, with patent or widely parted branches densely arising near to each other. Longer shoots pinnately branched in disticho-alternate manner with broader or slenderer, shorter or longer laciniae, or with sooner or later limited similarly pinnated short lateral branches. Laciniae grow together in more or less congenital manner; in adult ones each lacinia furnished with isolated, well-defined single apical cell, while in younger ones 2 or 3 apical cells are seen growing in a congenital manner as shown in Pl. CXCVII, fig. 10 and older stunted branches on the basal portion of frond is often much expanded with flabellately running midribs (fig. 12). Monosiphonous hairs entirely wanting.

—*Tetraspores* formed in the lacininae of the upper segment in one longitudinal row. *Colour* vinoso-red. *Substance* membranaceous and the plant does not adhere to paper in drying.

Hab.: on the frond of other algae, Noh (Prov. Echigo).

The present plant has been identified by late Prof. Yendo as *Pterosiphonia parasitica* Fkbg. It has a very close external appearance of *Pterosiphonia*, but as the congenital nature of apical portion of branches, especially of younger ones, tells its difference from that genus, it should be better to put the plant in question in *Symphyocladia*.

Of all the species of *Symphyocladia* known in this country the present plant stands very near by *S. linearis* Okam. which differs by having very much elongated fronds. With exception of the difference of size the two plants resemble in having much separated laciniae. On the other hand, the plant in question has an appearance very closely resembling the narrower form of *S. marchantioides* (Harv.) Fkbg., from which however it differs in having much separated laciniae.

Taking into consideration that the water of the Japan Sea is always a little colder than that of the Pacific of this country and that the plant of one and the same species often takes much a different form and appearance in the both waters, I am in doubt whether the present plant is not a dwarf variety of *S. linearis* Okam. or a narrower form of *S. marchantioides*. But at present I refer it provisionally as a new species.

Trichogloea lubrica (Harv.) J. Ag.

Nom. Jap.: *Akebonomozuku*.

PL. CXCvII, Fig. 1-8.

Trichogloea lubrica (Harv.) J. Ag. Epicr. p. 514; Id. Till Alg. Syst. XI, p. 41; De Toni Syll. Alg. IV, p. 77.—*Helminthocladia Cassei* Crouan in Mazé and Schramm Alg. Guadel. p. 177.

Root a small soft disc. *Frond* mostly simple, filiform or cylindrical, weak, tapering at base, pinnately branched decomposed, in irregularly alternate manner. Main stem mostly simple or parted, closely set through its whole length with patent branches equally thick as stem, scarcely 1.5 mm. in thickness with thinly encrustated axis whose diameter is much less than the thickness of peripheral layer. Branches worm-like, usually not attenuated at base, tapering to a slender apex, loaded with lateral simple or forked patent branchlets with longer or shorter ones mixed.—*Cystocarps* dot-like, situated in the peripheral layer and consist of a globular mass of spores. *Colour* beautiful red soon fading in freshwater. *Substance* soft, gelatinoso-mucose, lubricous and the plant closely adheres to paper in drying.

Hab.: on rocks between tide-marks near low tide. Ryukyu (Harv.), Nomo-zaki, Hachijo-Shima.

Plocamium costatum (J. Ag.) Hook. et Harv.

Nom. Jap.: *Kisami-yukari*.

PL. CXCVIII, Fig. 1-4.

Plocamium costatum (J. Ag.) Hook. et Harv.; Yendo Notes on Algae New to Jap. VIII, (Bot. Mag. Tokyo, vol XXXII, n. 376, p. 68, 1918); Harv. Ner. Aust. p. 122 partim; Kg. Sp. Alg. p. 886; Id. Tab. Phyc. vol. XVI, t. 52, f. *d-e*; J. Ag. Sp. Alg. II, p. 403; Id. Epicr. p. 344; De Toni Syll. Alg. IV, p. 597.

Only one specimen now before us. *Fronde* flat, linear, thin membranaceous, about 7 cm. high, scarcely 1 mm. broad, gently flexuose. Branches distichous, 2-4 times decomposed pinnate, alternate and erecto-patent, the lower ones longer than the upper and gradually becoming shorter above, so that the outline is somewhat corymbose; they are thought alternate in geminate manner (*i. e.* two on one side and as many on the other), of which the lower one is always simple, while the upper decomposed; the simple one 2-3 mm. long, tapering to a fine point from broader base, widely parted in lower or middle ones, and more or less incurved in upper ones. The lower simple lacina of geminate ones furnished with microscopically minute teeth-like serrations along the outer margin.—*Sporophylls* forming divaricato-dichotome stellate clusters provided with a short pedicel composed of sublanceolate or linear ramuli, which is transformed from lacinulae.

Hab.: Kōtōsho (Taiwan).

Our plant seems to differ from the typical one in not having the midrib and basal stem-like portion. Habit, texture and mode of branching are very similar to *Pl. abnorme* H. et H. (Pl. CI of the present Icones), only differing in having serrated margin on the outer side of the simple lacina of geminate ones. The plant now in consideration may probably be a form which grows on the northernmost limit of the distribution of the present species and as consequence having much smaller size, thin, fine and membranaceous texture, and the midrib invisible or not manifest. A hybrid of *Pl. abnorme* and *Pl. costatum*?

Pl. CXC VIII, fig. 1-4. Fig. 1: frond of *Plocamium costatum* H. et H., $\frac{1}{1}$.—Fig. 2: upper portion of branch, $\frac{22}{1}$.—Fig. 3: sporophylls, $\frac{48}{1}$.—Fig. 4: sporophyll; *b*, pedicel, $\frac{48}{1}$.

Dasyphila plumarioides Yendo.

Nom. Jap.: *Okishinobu*.

PL. CXC VIII, Fig. 5-11.

Dasyphila plumarioides Yendo Nov. Alg. Jap. Decas I-III (Bot. Mag. Tokyo Vol. 34, p. 7, 1920).

Frond filiform, little thickening below to subcylindrical stem, gradually compressed upward, irregularly alternately decompose with patent branches, expanding in a subflabellate manner. Branches are loaded with elegant pinnae (*k, k* in fig. 10-11). Pinnae which arise in opposite manner sooner or later make limited growth and are callithamnioid that is consist of single row of cells. They are alternately pinnulated with pinnulae arising from every articulation of the rachis. One of pinnae standing opposite may grow up into branch (*l, l* in fig. 10-11) and branch usually arises from every second node (*i.e.*, intervening a pair of

F. Crani del.

Homoeostrichus Sinclairii (Het H.) J. Ag. やぶれあぶぎ Fig. 1-4.
Desmarestia aculeata (L.) Lamour. とげうるいぐさ Fig. 5-9.

pinnæ) (fig. 10); but this rule is often disturbed, there being some irregularities so as to intervene one or three articulations (fig. 11 *a, b*). On the surface of branches two weakly developed moniliform filaments or hairs are seen at articulations (fig. 7). That these hairs are really simple moniliform branch consisting of 2-4 articulations and remaining in non-developing state is seen in a very young branch which is composed of simple moniliform row of cells and still having no cortical cell (fig. 6). On the cross-section of branch a large central axis is seen surrounded by 6 larger cells, two of which standing at frank side give rise to pinnæ and other remain either undeveloped or grow to simple moniliform hair-like branch consisting of a few articulations. Cortical layer is produced as rhizoid-cells arising from the basal cell of lateral branches (fig. 6).—*Tetraspores* produced on the terminal cell of pinnule, roundish, tripartite.

Hab.: Kōtōsho (Taiwan).

Gelidium crinale (Turn.) Lamour. f. *latifolium* n. f.

Nom. Jap.: *Itotengusa*.

PL. CXC VIII, Fig. 12.

*Fronde*s linear, erect, standing from creeping and rooting stolon, filiform and naked below, 5-6 cm. long, dilating to narrow-linear segments; 1-1.5 mm. broad which give rise to slender similar-shaped linear branches irregularly arising in alternate,

clustered or scattered manner. They are gradually or abruptly tapering toward their bases and end in blunt apices.

Hab.: on shallow place at Kamakura (Higashi).

A form distinguished from the typical form by having a rather broader narrow-linear segments.

Caulerpa cupressoides C. Ag. var. **typica** Web. v. Bos.

びやくしんづたノ一品種

第 CC 圖版, 2 圖.

今唯一個ノ標品アルノミ. 匍枝ハ太ク, 圓柱狀ニシテ裸出ス. 體ハ基部圓柱狀ニシテ上方ニ扁壓ス. ラメンタ(即チ羽狀ニ出ル 缺刻)ハ兩縁ヨリ出デ其處此處ニ三列ヲナシ, 稍小舟狀ニシテ短ク, 直立シ又ハ少シク廣開ス.

產地: 紀州椒村.

第 CC 圖版, 2 圖: *Caulerpa cupressoides* C. Ag. var. *typica* Web. v. Bos. ノ體ノ一部, $\frac{1}{1}$.

Caulerpa cupressoides C. Ag. var. **lycopodioides**
f. **elegans** Web. v. Bos.

びやくしんづたノ一品種

第 CC 圖版, 3 圖.

匍枝ハ太ク, 強ク, 裸出シ, 圓柱狀ナリ. 體ハ高ク挺出シ, 圓柱狀ニシテ下部太ク, 枝ヲ出シ, 枝ハ基部ニ「ラメンタ」ナシ. ラメンタ(櫛齒狀ノ枝)ハ兩縁ヨリ出デ, 稍小舟狀ヲナシ, 枝ノ軸ノ幅ノ 2-3 倍長シ.

產地: 紀州椒村.

第 CC 圖版, 3 圖: *Caulerpa cupressoides* C. Ag. var. *lycopodioides* f. *elegans* ノ體ノ一部, $\frac{1}{1}$.

Derbesia Solier つゆのいと屬.

DERBESIACEAE つゆのいと科

體ハ實ナキ状態ニテハ單細胞ニシテ, 單條又ハ不規則ニ若クハ叉狀ニ分岐シ, 莖及葉ノ如キ明ナル區別ヲ有セズ. 游走子ハ體ノ側面ニ特ニ形成セラレタル子囊中ニ形成セラレ, 他ノ部ト隔膜ヲ以テ分タル. 游走子ハ大

ニシテ無色ナル前端ノ基部ニ環狀ニ纖毛ヲ冠ス。一屬ノ名ハ佛國ノ海藻學者 E. Derbes 氏ノ名ニ因ル。

S-10 種アリテ石又ハ他ノ海藻上ニ存シ、海産ニシテ歐州、北米、オーストラリアニ知ラレタリ。

Derbesia Lamourouxii (J. Ag.) Sol.

つゆのいと 岡村 稱

第 CC 圖版, 4-8 圖

體ハ絲狀、毛細狀、密ニ叢生シテ團塊ヲナシ、高サ 5-6 cm. アリ。絲ハ 170-615 μ 太ク(乾燥標品ニテ)、下部ヨリ根ヲ出シ、枝ナクシテ殆ド單條又ハ不規則ニ小サキ枝ヲ出ス。子囊ハ球狀ニシテ直徑約 350 μ ア、無柄(或ハ短キ柄アリ)、單獨又ハ數個相接シテ出デ又ハ一方ノ側ニ偏在ス。

產地：紀州椒村。

第 CC 圖版, 4-8 圖。4: *Derbesia Lamourouxii*, (J. Ag.) Sol., つゆのいと, ノ叢, $\frac{1}{1}$ 。—5: 子囊ヲ有スル枝, $\frac{1}{1}$ 。—6: 枝ノ上部ヨリ出タル根, $\frac{48}{1}$ 。—7: 子囊, $\frac{48}{1}$ 。

正 誤

78 頁下ヨリ七行: *Cladophoropsis fasciculatus* ハ *Cl. coriacea* ノ誤。

INDEX

索引

Roman numerals indicate pages for English, and those in *Italics* for Japanese; Synonyms are printed in *Italics* and Plates in Arabian numerals.

羅馬數字ハ英文ノ頁ヲ示シ、日本數字ハ和文ノ頁ヲ示ス。又亞刺比亞數字ハ圖版ノ番號ニシテ草體ノ學名ハ異稱ナリ。
